Preface

This preface introduces the Cortex-M0 Devices Generic User Guide. It contains the following sections:

• About this book on page viii
• Feedback on page xi.
About this book

This book is a generic user guide for devices that implement the ARM Cortex-M0 processor. Implementers of Cortex-M0 designs make a number of implementation choices, that can affect the functionality of the device. This means that, in this book:

- some information is described as implementation-defined
- some features are described as optional.

See the documentation from the supplier of your Cortex-M0 device for more information about these features.

In this book, unless the context indicates otherwise:

**Processor**  Refers to the Cortex-M0 processor, as supplied by ARM.

**Device**  Refers to an implemented device, supplied by an ARM partner, that incorporates a Cortex-M0 processor. In particular, *your device* refers to the particular implementation of the Cortex-M0 that you are using. Some features of your device depend on the implementation choices made by the ARM partner that made the device.

Product revision status

The *rn*pn identifier indicates the revision status of the product described in this book, where:

- *rn* Identifies the major revision of the product.
- *pn* Identifies the minor revision or modification status of the product.

Intended audience

This book is written for application and system-level software developers, familiar with programming, who want to program a device that includes the Cortex-M0 processor.

Using this book

This book is organized into the following chapters:

**Chapter 1 Introduction**  
Read this for an introduction to the Cortex-M0 processor and its features.

**Chapter 2 The Cortex-M0 Processor**  
Read this for information about how to program the processor, the processor memory model, exception and fault handling, and power management.
Preface

Chapter 3 The Cortex-M0 Instruction Set
Read this for information about the processor instruction set.

Chapter 4 Cortex-M0 Peripherals
Read this for information about Cortex-M0 peripherals.

Appendix A Cortex-M0 Options
Read this for information about the processor implementation and configuration options.

Glossary
Read this for definitions of terms used in this book.

Typographical conventions
The typographical conventions used in this document are:

italic Highlights important notes, introduces special terminology, denotes internal cross-references, and citations.

bold Used for terms in descriptive lists, where appropriate.

monospace Denotes text that you can enter at the keyboard, such as commands, file and program names, and source code.

monospace italic Denotes arguments to monospace text where the argument is to be replaced by a specific value.

< and > Enclose replaceable terms for assembler syntax where they appear in code or code fragments. For example:

CMP Rn, <Rm|imm>
Additional reading

This section lists publications by ARM and by third parties.

See onARM, http://onarm.com, for embedded software development resources including the Cortex Microcontroller Software Interface Standard (CMSIS).

ARM publications

This book contains information that is specific to this product. See the following documents for other relevant information:

- Cortex-M0 Technical Reference Manual (ARM DDI 0432)

Other publications

This guide only provides generic information for devices that implement the ARM Cortex-M0 processor. For information about your device see the documentation published by the device manufacturer.
Feedback

ARM welcomes feedback on this product and its documentation.

Feedback on this product

If you have any comments or suggestions about this product, contact your supplier and give:

• The product name.
• The product revision or version.
• An explanation with as much information as you can provide. Include symptoms and diagnostic procedures if appropriate.

Feedback on content

If you have comments on content then send an e-mail to errata@arm.com. Give:

• the title
• the number, ARM DUI 0497A
• the page numbers to which your comments apply
• a concise explanation of your comments.

ARM also welcomes general suggestions for additions and improvements.
Chapter 1
Introduction

This chapter introduces the Cortex-M0 processor and its features. It contains the following section:

• About the Cortex-M0 processor and core peripherals on page 1-2.
1.1 About the Cortex-M0 processor and core peripherals

The Cortex™-M0 processor is an entry-level 32-bit ARM Cortex processor designed for a broad range of embedded applications. It offers significant benefits to developers, including:

- simple, easy-to-use programmers model
- highly efficient ultra-low power operation
- excellent code density
- deterministic, high-performance interrupt handling
- upward compatibility with the rest of the Cortex-M processor family.

The Cortex-M0 processor is built on a high-performance processor core, with a 3-stage pipeline von Neumann architecture, making it ideal for demanding embedded applications. The processor is extensively optimized for low power and area, and delivers exceptional power efficiency through its efficient instruction set, providing high-end processing hardware including either:

- a single-cycle multiplier, in designs optimized for high performance
- a 32-cycle multiplier, in designs optimized for low area.

The Cortex-M0 processor implements the ARMv6-M architecture, that implements the ARMv6-M Thumb® instruction set, including Thumb-2 technology. This provides the exceptional performance expected of a modern 32-bit architecture, with a higher code density than other 8-bit and 16-bit microcontrollers.

The Cortex-M0 processor closely integrates a configurable Nested Vectored Interrupt Controller (NVIC), to deliver industry-leading interrupt performance. The NVIC:

- includes a non-maskable interrupt (NMI)

Figure 1-1 Cortex-M0 implementation

The Cortex-M0 processor is built on a high-performance processor core, with a 3-stage pipeline von Neumann architecture, making it ideal for demanding embedded applications. The processor is extensively optimized for low power and area, and delivers exceptional power efficiency through its efficient instruction set, providing high-end processing hardware including either:

- a single-cycle multiplier, in designs optimized for high performance
- a 32-cycle multiplier, in designs optimized for low area.

The Cortex-M0 processor implements the ARMv6-M architecture, that implements the ARMv6-M Thumb® instruction set, including Thumb-2 technology. This provides the exceptional performance expected of a modern 32-bit architecture, with a higher code density than other 8-bit and 16-bit microcontrollers.

The Cortex-M0 processor closely integrates a configurable Nested Vectored Interrupt Controller (NVIC), to deliver industry-leading interrupt performance. The NVIC:

- includes a non-maskable interrupt (NMI)
The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing the interrupt latency. This is achieved through the hardware stacking of registers, and the ability to abandon and restart load-multiple and store-multiple operations. Interrupt handlers do not require any assembler wrapper code, removing any code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another.

To optimize low-power designs, the NVIC integrates with sleep mode. Optionally, sleep mode support can include a deep sleep function that enables the entire device to be rapidly powered down.

1.1.1 System-level interface

The Cortex-M0 processor provides a single system-level interface using AMBA® technology to provide high speed, low latency memory accesses.

1.1.2 Optional integrated configurable debug

The Cortex-M0 processor can implement a complete hardware debug solution, with extensive hardware breakpoint and watchpoint options. This provides high system visibility of the processor, memory and peripherals through a JTAG port or a 2-pin Serial Wire Debug (SWD) port that is ideal for microcontrollers and other small package devices. The MCU vendor determines the implemented debug features, and therefore this is device-dependent.

1.1.3 Cortex-M0 processor features summary

- high code density with 32-bit performance
- tools and binaries upwards-compatible across the Cortex-M processor family
- integrated low-power sleep modes
- fast code execution permits slower processor clock or increases sleep mode time
- hardware multiplier
- zero-jitter interrupt handling
- extensive debug capabilities.
1.1.4 Cortex-M0 core peripherals

The Cortex-M0 core peripherals are:

**NVIC**  
An embedded interrupt controller that supports low latency interrupt processing.

**System Control Block**  
The *System Control Block* (SCB) is the programmers model interface to the processor. It provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

**Optional system timer**  
The optional system timer, SysTick, is a 24-bit count-down timer. If implemented, use this as a *Real Time Operating System* (RTOS) tick timer or as a simple counter.
Chapter 2
The Cortex-M0 Processor

The following sections describe the Cortex-M0 processor:

- *Programmers model* on page 2-2
- *Memory model* on page 2-12
- *Exception model* on page 2-19
- *Fault handling* on page 2-27
2.1 Programmers model

This section describes the Cortex-M0 programmers model. In addition to the individual core register descriptions, it contains information about the processor modes and stacks.

2.1.1 Processor modes

The processor modes are:

- **Thread mode**: Used to execute application software. The processor enters Thread mode when it comes out of reset.

- **Handler mode**: Used to handle exceptions. The processor returns to Thread mode when it has finished all exception processing.

2.1.2 Stacks

The processor uses a full descending stack. This means the stack pointer indicates the last stacked item on the stack memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location. The processor implements two stacks, the **main stack** and the **process stack**, with independent copies of the stack pointer, see *Stack Pointer* on page 2-4.

In Thread mode, the CONTROL register controls whether the processor uses the main stack or the process stack, see *CONTROL register* on page 2-9. In Handler mode, the processor always uses the main stack. The options for processor operations are:

<table>
<thead>
<tr>
<th>Processor mode</th>
<th>Used to execute</th>
<th>Stack used</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thread</td>
<td>Applications</td>
<td>Main stack or process stack&lt;sup&gt;a&lt;/sup&gt;</td>
</tr>
<tr>
<td>Handler</td>
<td>Exception handlers</td>
<td>Main stack</td>
</tr>
</tbody>
</table>

<sup>a</sup> See *CONTROL register* on page 2-9
2.1.3 Core registers

The processor core registers are:

- **Low registers**
  - R0-R12
- **High registers**
  - MSP
  - PSP
- **General purpose registers**
  - PC
  - LR
  - R0-R12
- **Special registers**
  - Control Register
  - Program Status Register
  - PRIMASK

### Table 2-2 Core register set summary

<table>
<thead>

</tbody>
</table>

*Type: RW = Read-Write, RO = Read-Only, Reset value indicates default value.*

*Unknown b indicates a special case where the reset value is not specified.*
General-purpose registers
R0-R12 are 32-bit general-purpose registers for data operations.

Stack Pointer
The Stack Pointer (SP) is register R13. In Thread mode, bit[1] of the CONTROL register indicates the stack pointer to use:
- 0 = Main Stack Pointer (MSP). This is the reset value.
- 1 = Process Stack Pointer (PSP).

On reset, the processor loads the MSP with the value from address 0x00000000.

Link Register
The Link Register (LR) is register R14. It stores the return information for subroutines, function calls, and exceptions. On reset, the LR value is Unknown.

Program Counter
The Program Counter (PC) is register R15. It contains the current program address. On reset, the processor loads the PC with the value of the reset vector, at address 0x00000004. Bit[0] of the value is loaded into the EPSR T-bit at reset and must be 1.

Program Status Register
The Program Status Register (PSR) combines:
- Application Program Status Register (APSR)
- Interrupt Program Status Register (IPSR)
- Execution Program Status Register (EPSR).

Table 2-2 Core register set summary (continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Type*</th>
<th>Reset value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRIMASK</td>
<td>RW</td>
<td>0x00000000</td>
<td>Priority Mask Register on page 2-9</td>

<tr>
<td>CONTROL</td>
<td>RW</td>
<td>0x00000000</td>
<td>CONTROL register on page 2-9</td>
</tr>
</tbody>
</table>

a. Describes access type during program execution in thread mode and Handler mode. Debug access can differ.
b. Bit[24] is the T-bit and is loaded from bit[0] of the reset vector.
These registers are mutually exclusive bitfields in the 32-bit PSR. The PSR bit assignments are:

<table>
<thead>
<tr>
<th>31 30 29 28</th>
<th>27 25 24 23</th>
<th>22 21 20 19</th>
<th>18 17 16 15</th>
<th>14 13 12 11</th>
<th>10  9  8  7</th>
<th>6  5  4  3</th>
<th>2   1  0</th>
</tr>
</thead>
<tbody>
<tr>
<td>APSR</td>
<td>N  Z  C  V</td>
<td>Reserved</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>IPSR</td>
<td>Reserved</td>
<td></td>
<td>Exception number</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EPSR</td>
<td>Reserved</td>
<td>T</td>
<td>Reserved</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Access these registers individually or as a combination of any two or all three registers, using the register name as an argument to the MSR or MRS instructions. For example:
- read all of the registers using PSR with the MRS instruction
- write to the APSR using APSR with the MSR instruction.

The PSR combinations and attributes are:

<table>
<thead>
<tr>
<th>Table 2-3 PSR register combinations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Register</td>
</tr>
<tr>
<td>----------</td>
</tr>
<tr>
<td>PSR</td>
</tr>
<tr>
<td>IEP SR</td>
</tr>
<tr>
<td>IAPS R</td>
</tr>
<tr>
<td>EAPS R</td>
</tr>
</tbody>
</table>

a. The processor ignores writes to the IPSR bits.
b. Reads of the EPSR bits return zero, and the processor ignores writes to these bits.

See the instruction descriptions MRS on page 3-54 and MSR on page 3-55 for more information about how to access the program status registers.
**Application Program Status Register**

The APSR contains the current state of the condition flags, from previous instruction executions. See the register summary in Table 2-2 on page 2-3 for its attributes. The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31]</td>
<td>N</td>
<td>Negative flag</td>
</tr>
<tr>
<td>[30]</td>
<td>Z</td>
<td>Zero flag</td>
</tr>
<tr>
<td>[29]</td>
<td>C</td>
<td>Carry or borrow flag</td>
</tr>
<tr>
<td>[28]</td>
<td>V</td>
<td>Overflow flag</td>
</tr>
<tr>
<td>[27:0]</td>
<td>-</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

See *The condition flags* on page 3-14 for more information about the APSR negative, zero, carry or borrow, and overflow flags.
Interrupt Program Status Register

The IPSR contains the exception number of the current ISR. See the register summary in Table 2-2 on page 2-3 for its attributes. The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:6]</td>
<td></td>
<td>Reserved</td>
</tr>
<tr>
<td>[5:0]</td>
<td>Exception number</td>
<td>This is the number of the current exception:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = Thread mode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = Reserved</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2 = NMI</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3 = HardFault</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4-10 = Reserved</td>
</tr>
<tr>
<td></td>
<td></td>
<td>11 = SVCall</td>
</tr>
<tr>
<td></td>
<td></td>
<td>12, 13 = Reserved</td>
</tr>
<tr>
<td></td>
<td></td>
<td>14 = PendSV</td>
</tr>
<tr>
<td></td>
<td></td>
<td>15 = SysTick, if implemented^b</td>
</tr>
<tr>
<td></td>
<td></td>
<td>16 = IRQ0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>.</td>
</tr>
<tr>
<td></td>
<td>n+15 = IRQ(n-1)^b</td>
<td></td>
</tr>
<tr>
<td></td>
<td>(n+16) to 63 = Reserved.</td>
<td></td>
</tr>
</tbody>
</table>

Table 2-5 IPSR bit assignments

---

a. If the device does not implement the SysTick timer, exception number 15 is reserved.
b. The number of interrupts, n, is implementation-defined, in the range 1-32.

Execution Program Status Register

The EPSR contains the Thumb state bit.
See the register summary in Table 2-2 on page 2-3 for the EPSR attributes. The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:25]</td>
<td>-</td>
<td>Reserved</td>
</tr>
<tr>
<td>[24]</td>
<td>T</td>
<td>Thumb state bit</td>
</tr>
<tr>
<td>[23:0]</td>
<td>-</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Attempts by application software to read the EPSR directly using the MRS instruction always return zero. Attempts to write the EPSR using the MSR instruction are ignored. Fault handlers can examine the EPSR value in the stacked PSR to determine the cause of the fault. See Exception entry and return on page 2-23. The following can clear the T bit to 0:

- instructions BLX, BX and POP{PC}
- restoration from the stacked xPSR value on an exception return
- bit[0] of the vector value on an exception entry.

Attempting to execute instructions when the T bit is 0 results in a HardFault or lockup. See Lockup on page 2-27 for more information.

**Interruptible-restartable instructions**

When an interrupt occurs during the execution of an LDM or STM instruction, the processor abandons the load multiple or store multiple operation, and similarly abandons a multiply instruction if it implements this as a 32-cycle instruction.

After servicing the interrupt, the processor restarts execution of the abandoned instruction from the beginning.

**Exception mask register**

The exception mask register disables the handling of exceptions by the processor. Disable exceptions where they might impact on timing critical tasks or code sequences requiring atomicity.

To disable or re-enable exceptions, use the MSR and MRS instructions, or the CPS instruction, to change the value of PRIMASK. See MRS on page 3-54, MSR on page 3-55, and CPS on page 3-50 for more information.
**Priority Mask Register**

The PRIMASK register prevents activation of all exceptions with configurable priority. See the register summary in Table 2-2 on page 2-3 for its attributes. The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:1]</td>
<td>-</td>
<td>Reserved</td>
</tr>
</tbody>
</table>
| [0]   | PRIMASK| 0 = no effect  
                   | 1 = prevents the activation of all exceptions with configurable priority. |

**CONTROL register**

The CONTROL register controls the stack used when the processor is in Thread mode. See the register summary in Table 2-2 on page 2-3 for its attributes. The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:2]</td>
<td>-</td>
<td>Reserved</td>
</tr>
</tbody>
</table>
| [1]  | Active stack pointer | Defines the current stack:  
  0 = MSP is the current stack pointer  
  1 = PSP is the current stack pointer.  
  In Handler mode this bit reads as zero and ignores writes. |
| [0]  | -                  | Reserved.                                      |
Handler mode always uses the MSP, so the processor ignores explicit writes to the active stack pointer bit of the CONTROL register when in Handler mode. The exception entry and return mechanisms update the CONTROL register.

In an OS environment, ARM recommends that threads running in Thread mode use the process stack and the kernel and exception handlers use the main stack.

By default, Thread mode uses the MSP. To switch the stack pointer used in Thread mode to the PSP, use the MSR instruction to set the Active stack pointer bit to 1, see MRS on page 3-54.

Note

When changing the stack pointer, software must use an ISB instruction immediately after the MSR instruction. This ensures that instructions after the ISB execute using the new stack pointer. See ISB on page 3-53.

2.1.4 Exceptions and interrupts

The Cortex-M0 processor supports interrupts and system exceptions. The processor and the NVIC prioritize and handle all exceptions. An interrupt or exception changes the normal flow of software control. The processor uses handler mode to handle all exceptions except for reset. See Exception entry on page 2-24 and Exception return on page 2-25 for more information.

The NVIC registers control interrupt handling. See Nested Vectored Interrupt Controller on page 4-3 for more information.

2.1.5 Data types

The processor:

• supports the following data types:
  — 32-bit words
  — 16-bit halfwords
  — 8-bit bytes

• manages all data memory accesses as either little-endian or big-endian, depending on the device implementation. Instruction memory and Private Peripheral Bus (PPB) accesses are always little-endian. See Memory regions, types and attributes on page 2-13 for more information.
2.1.6  The Cortex Microcontroller Software Interface Standard

ARM provides the Cortex Microcontroller Software Interface Standard (CMSIS) for programming Cortex-M0 microcontrollers. The CMSIS is an integrated part of the device driver library. For a Cortex-M0 microcontroller system, CMSIS defines:

- a common way to:
  - access peripheral registers
  - define exception vectors
- the names of:
  - the registers of the core peripherals
  - the core exception vectors
- a device-independent interface for RTOS kernels.

The CMSIS includes address definitions and data structures for the core peripherals in a Cortex-M0 processor. It also includes optional interfaces for middleware components comprising a TCP/IP stack and a Flash file system.

The CMSIS simplifies software development by enabling the reuse of template code, and the combination of CMSIS-compliant software components from various middleware vendors. Software vendors can expand the CMSIS to include their peripheral definitions and access functions for those peripherals.

This document includes the register names defined by the CMSIS, and gives short descriptions of the CMSIS functions that address the processor core and the core peripherals.

Note

This document uses the register short names defined by the CMSIS. In a few cases these differ from the architectural short names that might be used in other documents.

The following sections give more information about the CMSIS:

- Power management programming hints on page 2-30
- Intrinsic functions on page 3-5
- Accessing the Cortex-M0 NVIC registers using CMSIS on page 4-3
- NVIC programming hints on page 4-9.
2.2 Memory model

This section describes the memory map of a Cortex-M0 device and the behavior of memory accesses. The processor has a fixed memory map that provides up to 4GB of addressable memory. The memory map is:

- **Device**: 511MB, starting at 0xFFFFFFFF
- **Private peripheral bus**: 1MB, starting at 0xE0100000
- **External device**: 1.0GB, starting at 0xA0000000
- **External RAM**: 1.0GB, starting at 0xDFFFFFFF
- **Peripheral**: 0.5GB, starting at 0x60000000
- **SRAM**: 0.5GB, starting at 0x20000000
- **Code**: 0.5GB, starting at 0x00000000

The processor reserves regions of the PPB address range for core peripheral registers, see *About the Cortex-M0 processor and core peripherals* on page 1-2.
2.2.1 Memory regions, types and attributes

The memory map is split into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

**Normal**
- The processor can re-order transactions for efficiency, or perform speculative reads.

**Device**
- The processor preserves transaction order relative to other transactions to Device or Strongly-ordered memory.

**Strongly-ordered**
- The processor preserves transaction order relative to all other transactions.

The different ordering requirements for Device and Strongly-ordered memory mean that the memory system can buffer a write to Device memory, but must not buffer a write to Strongly-ordered memory.

The additional memory attributes include.

**Shareable**
- For a shareable memory region, the memory system provides data synchronization between bus masters in a system with multiple bus masters, for example, a device with a DMA controller. Strongly-ordered memory is always shareable.

If multiple bus masters can access a non-shareable memory region, software must ensure data coherency between the bus masters.

--- Note ---
This attribute is relevant only if the device is likely to be used in systems where memory is shared between multiple processors.

**Execute Never (XN)**
- Means the processor prevents instruction accesses. A HardFault exception is generated on executing an instruction fetched from an XN region of memory.
2.2.2 Memory system ordering of memory accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing any re-ordering does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions, see Software ordering of memory accesses on page 2-16.

However, the memory system does guarantee some ordering of accesses to Device and Strongly-ordered memory. For two memory access instructions A1 and A2, if A1 occurs before A2 in program order, the ordering of the memory accesses caused by two instructions is:

<table>
<thead>
<tr>
<th>A1</th>
<th>Normal access</th>
<th>Device access</th>
<th>Strongly-ordered access</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Normal access</td>
<td>Device access</td>
<td>Strongly-ordered access</td>
</tr>
<tr>
<td>Normal access</td>
<td>-</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>Device access, non-shareable</td>
<td>-</td>
<td>&lt;</td>
<td>-</td>
</tr>
<tr>
<td>Device access, shareable</td>
<td>-</td>
<td>-</td>
<td>&lt;</td>
</tr>
<tr>
<td>Strongly-ordered access</td>
<td>-</td>
<td>&lt;</td>
<td>&lt;</td>
</tr>
</tbody>
</table>

Where:

- Means that the memory system does not guarantee the ordering of the accesses.

< Means that accesses are observed in program order, that is, A1 is always observed before A2.
2.2.3 Behavior of memory accesses

The behavior of accesses to each region in the memory map is:

<table>
<thead>
<tr>
<th>Address range</th>
<th>Memory region</th>
<th>Memory type</th>
<th>XN</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00000000-0x1FFFFFFF</td>
<td>Code</td>
<td>Normal</td>
<td>-</td>
<td>Executable region for program code. You can also put data here.</td>
</tr>
<tr>
<td>0x20000000-0x3FFFFFFF</td>
<td>SRAM</td>
<td>Normal</td>
<td>-</td>
<td>Executable region for data. You can also put code here.</td>
</tr>
<tr>
<td>0x40000000-0x5FFFFFFF</td>

<td>External device memory.</td>
</tr>
<tr>
<td>0xE0000000-0xE00FFFFF</td>
<td>Private Peripheral Bus</td>
<td>Strongly-ordered</td>
<td>XN</td>
<td>This region includes the NVIC, System timer, and System Control Block. Only word accesses can be used in this region.</td>
</tr>
<tr>
<td>0xE0100000-0xFFFFFFFF</td>
<td>Device</td>
<td>Device</td>
<td>XN</td>
<td>Implementation-specific.</td>
</tr>
</tbody>
</table>

Table 2-9 Memory access behavior

a. See Memory regions, types and attributes on page 2-13 for more information.

The Code, SRAM, and external RAM regions can hold programs.

Additional memory access constraints for caches and shared memory

When a system includes caches or shared memory, some memory regions have additional access constraints, and some regions are subdivided, as Table 2-10 shows:

<table>
<thead>
<tr>
<th>Address range</th>
<th>Memory region</th>
<th>Memory type</th>
<th>Shareability</th>
<th>Cache policy</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00000000-0x1FFFFFFF</td>
<td>Code</td>
<td>Normal</td>
<td>-</td>
<td>WT</td>
</tr>
<tr>
<td>0x20000000-0x3FFFFFFF</td>
<td>SRAM</td>
<td>Normal</td>
<td>-</td>
<td>WBWA</td>
</tr>
<tr>
<td>0x40000000-0x5FFFFFFF</td>
<td>Peripheral</td>
<td>Device</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>
2.2.4 Software ordering of memory accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions. This is because:

- the processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence
- memory or devices in the memory map might have different wait states
- some memory accesses are buffered or speculative.

Memory system ordering of memory accesses on page 2-14 describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The processor provides the following memory barrier instructions:

- **DMB**
  The Data Memory Barrier (DMB) instruction ensures that outstanding memory transactions complete before subsequent memory transactions. See DMB on page 3-51.

- **DSB**
  The Data Synchronization Barrier (DSB) instruction ensures that outstanding memory transactions complete before subsequent instructions execute. See DSB on page 3-52.

- **ISB**
  The Instruction Synchronization Barrier (ISB) ensures that the effect of all completed memory transactions is recognizable by subsequent instructions. See ISB on page 3-53.
The following are examples of using memory barrier instructions:

**Vector table**

If the program changes an entry in the vector table, and then enables the corresponding exception, use a **DMB** instruction between the operations. This ensures that if the exception is taken immediately after being enabled the processor uses the new exception vector.

**Self-modifying code**

If a program contains self-modifying code, use an **ISB** instruction immediately after the code modification in the program. This ensures subsequent instruction execution uses the updated program.

**Memory map switching**

If the system contains a memory map switching mechanism, use a **DSB** instruction after switching the memory map. This ensures subsequent instruction execution uses the updated memory map.

Memory accesses to Strongly-ordered memory, such as the System Control Block, do not require the use of **DMB** instructions.

### 2.2.5 Memory endianness

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word. The memory endianness used is implementation-defined, and the following subsections describe the possible implementations:

- **Byte-invariant big-endian format** on page 2-18
- **Little-endian format** on page 2-18.

Read the AIRCR.ENDIANNESS field to find the implemented endianness, see *Application Interrupt and Reset Control Register* on page 4-15.
Byte-invariant big-endian format

In byte-invariant big-endian format, the processor stores the most significant byte (msbyte) of a word at the lowest-numbered byte, and the least significant byte (lsbyte) at the highest-numbered byte. For example:

<table>
<thead>
<tr>
<th>Memory</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B0 msbyte</td>
</tr>
<tr>
<td>A+1</td>
<td>B1</td>
</tr>
<tr>
<td>A+2</td>
<td>B2</td>
</tr>
<tr>
<td>A+3</td>
<td>B3 lsbyte</td>
</tr>
</tbody>
</table>

Little-endian format

In little-endian format, the processor stores the lsbyte of a word at the lowest-numbered byte, and the msbyte at the highest-numbered byte. For example:

<table>
<thead>
<tr>
<th>Memory</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B0 lsbyte</td>
</tr>
<tr>
<td>A+1</td>
<td>B1</td>
</tr>
<tr>
<td>A+2</td>
<td>B2</td>
</tr>
<tr>
<td>A+3</td>
<td>B3 msbyte</td>
</tr>
</tbody>
</table>
2.3 Exception model

This section describes the exception model.

2.3.1 Exception states

Each exception is in one of the following states:

**Inactive**

The exception is not active and not pending.

**Pending**

The exception is waiting to be serviced by the processor.

An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending.

**Active**

An exception that is being serviced by the processor but has not completed.

--- Note ---

An exception handler can interrupt the execution of another exception handler. In this case both exceptions are in the active state.

---

**Active and pending**

The exception is being serviced by the processor and there is a pending exception from the same source.

2.3.2 Exception types

The exception types are:

**Reset**

Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts in Thread mode.

**NMI**

An NMI can be signalled by a peripheral or triggered by software. This is the highest priority exception other than reset. It is permanently enabled and has a fixed priority of -2. NMIs cannot be:

- masked or prevented from activation by any other exception
- preempted by any exception other than Reset.
HardFault

A HardFault is an exception that occurs because of an error during normal or exception processing. HardFaults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority.

SVCall

A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers.

PendSV

PendSV is an interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active.

SysTick

If the device implements the SysTick timer, a SysTick exception is an exception the system timer generates when it reaches zero. Software can also generate a SysTick exception. In an OS environment, the device can use this exception as system tick.

Interrupt (IRQ)

An interrupt, or IRQ, is an exception signalled by a peripheral, or generated by a software request. All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor.

Table 2-11 Properties of the different exception types

<table>
<thead>
<tr>
<th>Exception number</th>
<th>IRQ number</th>
<th>Exception type</th>
<th>Priority</th>
<th>Vector address</th>
<th>Activation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>-</td>
<td>-</td>
</tr>
<tr>
<td>16 and above</td>
<td>0 and above</td>
<td>IRQ</td>
<td>Configurable</td>
<td>0x00000040 and above</td>
<td>Asynchronous</td>
</tr>
</tbody>
</table>
For an asynchronous exception, other than reset, the processor can continue executing instructions between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that Table 2-11 on page 2-20 shows as having configurable priority, see Interrupt Clear-enable Register on page 4-5.

For more information about HardFault, see Fault handling on page 2-27.

2.3.3 Exception handlers

The processor handles exceptions using:

**ISR**

The IRQ interrupts are the exceptions handled by ISRs.

**Fault handler**

HardFault is the only exception handled by the fault handler.

**System handlers**

NMI, PendSV, SVC, and SysTick, and HardFault are all system exceptions handled by system handlers.

2.3.4 Vector table

The vector table contains the reset value of the stack pointer, and the start addresses, also called exception vectors, for all exception handlers. Figure 2-1 on page 2-22 shows the order of the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is written in Thumb code.
The vector table is fixed at address 0x00000000.

### 2.3.5 Exception priorities

As Table 2-11 on page 2-20 shows, all exceptions have an associated priority, with:

- a lower priority value indicating a higher priority
- configurable priorities for all exceptions except Reset, HardFault, and NMI.
If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities see

- **System Handler Priority Registers** on page 4-18
- **Interrupt Priority Registers** on page 4-7.

**Note**

Configurable priority values are in the range 0-192, in steps of 64. The Reset, HardFault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

Assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

### 2.3.6 Exception entry and return

Descriptions of exception handling use the following terms:

**Preemption**

When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled.

When one exception preempts another, the exceptions are called nested exceptions. See **Exception entry** on page 2-24 for more information.

**Return**

This occurs when the exception handler is completed, and:

- there is no pending exception with sufficient priority to be serviced
- the completed exception handler was not handling a late-arriving exception.

The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See **Exception return** on page 2-25 for more information.
Tail-chaining

This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.

Late-arriving

This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved would be the same for both exceptions. On return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.

Exception entry

Exception entry occurs when there is a pending exception with sufficient priority and either:

- the processor is in Thread mode
- the new exception is of higher priority than the exception being handled, in which case the new exception preempts the exception being handled.

When one exception preempts another, the exceptions are nested.

Sufficient priority means the exception has greater priority than any limit set by the mask register, see Exception mask register on page 2-8. An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred to as stacking and the structure of eight data words is referred to as a stack frame. The stack frame contains the following information:

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame. The stack frame is aligned to a double-word address.
The stack frame includes the return address. This is the address of the next instruction in the interrupted program. This value is restored to the PC at exception return so that the interrupted program resumes.

The processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an EXC_RETURN value to the LR. This indicates the stack pointer corresponding to the stack frame and the operation mode the processor was in before the entry occurred.

If no higher priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

If another higher priority exception occurs during exception entry, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception. This is the late arrival case.

**Exception return**

Exception return occurs when the processor is in Handler mode and execution of one of the following instructions attempts to set the PC to an EXC_RETURN value:

- a **POP** instruction that loads the PC
- a **BX** instruction using any register.

The processor saves an EXC_RETURN value to the LR on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. Bits[31:4] of an EXC_RETURN value are 0xFFFFFFFF. When the processor loads a value matching this pattern to the PC it detects that the operation is not a normal branch operation and, instead, that the exception is complete. Therefore, it starts the exception return sequence. Bits[3:0] of the EXC_RETURN value indicate the required return stack and processor mode, as Table 2-12 on page 2-26 shows.
### Table 2-12 Exception return behavior

<table>
<thead>
<tr>
<th>EXC_RETURN</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xFFFFFFF1</td>
<td>Return to Handler mode. Exception return gets state from the main stack. Execution uses MSP after return.</td>
</tr>
<tr>
<td>0xFFFFFFF9</td>
<td>Return to Thread mode. Exception return gets state from MSP. Execution uses MSP after return.</td>
</tr>
<tr>
<td>0xFFFFFD0</td>
<td>Return to Thread mode. Exception return gets state from PSP. Execution uses PSP after return.</td>
</tr>
<tr>
<td>All other values</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>
2.4 Fault handling

Faults are a subset of exceptions, see Exception model on page 2-19. All faults result in the HardFault exception being taken or cause lockup if they occur in the NMI or HardFault handler. The faults are:

- execution of an SVC instruction at a priority equal or higher than SVCall
- execution of a BKPT instruction without a debugger attached
- a system-generated bus error on a load or store
- execution of an instruction from an XN memory address
- execution of an instruction from a location for which the system generates a bus fault
- a system-generated bus error on a vector fetch
- execution of an Undefined instruction
- execution of an instruction when not in Thumb-State as a result of the T-bit being previously cleared to 0
- an attempted load or store to an unaligned address.

**Note**

Only Reset and NMI can preempt the fixed priority HardFault handler. A HardFault can preempt any exception other than Reset, NMI, or another HardFault.

2.4.1 Lockup

The processor enters a lockup state if a fault occurs when executing the NMI or HardFault handlers, or if the system generates a bus error when unstacking the PSR on an exception return using the MSP. When the processor is in lockup state it does not execute any instructions. The processor remains in lockup state until one of the following occurs:

- it is reset
- a debugger halts it
- an NMI occurs and the current lockup is in the HardFault handler.

**Note**

If lockup state occurs in the NMI handler a subsequent NMI does not cause the processor to leave lockup state.
2.5 Power management

The Cortex-M0 processor sleep modes reduce power consumption. The sleep modes your device implements are implementation-defined, but they might be one or both of the following:

• a sleep mode that stops the processor clock
• a deep sleep mode that stops the system clock and switches off the PLL and flash memory.

If your device implements two sleep modes providing different levels of power saving, the SLEEPDEEP bit of the SCR selects which sleep mode is used, see System Control Register on page 4-16. For more information about the behavior of the sleep modes see the documentation supplied by your device vendor.

This section describes the mechanisms for entering sleep mode, and the conditions for waking up from sleep mode.

2.5.1 Entering sleep mode

This section describes the mechanisms software can use to put the processor into sleep mode.

The system can generate spurious wakeup events, for example a debug operation wakes up the processor. Therefore software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back in to sleep mode.

Wait for interrupt

The Wait For Interrupt instruction, WFI, causes immediate entry to sleep mode. When the processor executes a WFI instruction it stops executing instructions and enters sleep mode. See WFI on page 3-60 for more information.

Wait for event

The Wait For Event instruction, WFE, causes entry to sleep mode conditional on the value of a one-bit event register. When the processor executes a WFE instruction, it checks the value of the event register:

0 The processor stops executing instructions and enters sleep mode
1 The processor sets the register to zero and continues executing instructions without entering sleep mode.
See \textit{WFE} on page 3-59 for more information.

If the event register is 1, this indicates that the processor must not enter sleep mode on execution of a \textit{WFE} instruction. Typically, this is because of the assertion of an external event signal, or, in a multiprocessor system, because another processor has executed an \textit{SEV} instruction, see \textit{SEV} on page 3-57. Software cannot access this register directly.

\textbf{Sleep-on-exit}

If the SLEEPONEXIT bit of the SCR is set to 1, when the processor completes the execution of an exception handler and returns to Thread mode it immediately enters sleep mode. Use this mechanism in applications that only require the processor to run when an interrupt occurs.

\section*{2.5.2 Wakeup from sleep mode}

The conditions for the processor to wakeup depend on the mechanism that caused it to enter sleep mode.

\textbf{Wakeup from WFI or sleep-on-exit}

Normally, the processor wakes up only when it detects an exception with sufficient priority to cause exception entry.

Some embedded systems might have to execute system restore tasks after the processor wakes up, and before it executes an interrupt handler. To achieve this set the PRIMASK bit to 1. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor sets PRIMASK to zero. For more information about PRIMASK, see \textit{Exception mask register} on page 2-8.

\textbf{Wakeup from WFE}

The processor wakes up if:

- it detects an exception with sufficient priority to cause exception entry
- it detects an external event signal, see \textit{The external event signal} on page 2-30
- in a multiprocessor system, another processor in the system executes an \textit{SEV} instruction.
In addition, if the SEVONPEND bit in the SCR is set to 1, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about the SCR see System Control Register on page 4-16.

2.5.3 The optional Wakeup Interrupt Controller

Your device might include a Wakeup Interrupt Controller (WIC), an optional peripheral that can detect an interrupt and wake the processor from deep sleep mode. The WIC is enabled only when the DEEPSLEEP bit in the SCR is set to 1, see System Control Register on page 4-16.

The WIC is not programmable, and does not have any registers or user interface. It operates entirely from hardware signals.

When the WIC is enabled and the processor enters deep sleep mode, the power management unit in the system can power down most of the Cortex-M0 processor. This has the side effect of stopping the SysTick timer. When the WIC receives an interrupt, it takes a number of clock cycles to wakeup the processor and restore its state, before it can process the interrupt. This means interrupt latency is increased in deep sleep mode.

2.5.4 The external event signal

Your device might include an external event signals, that device peripherals can use to signal the processor, to wakeup the processor from WFE, or set the internal WFE event register to one to indicate that the processor must not enter sleep mode on a later WFE instruction. For more information see Wait for event on page 2-28. The documentation supplied by your device vendor might give more information about this signal.

2.5.5 Power management programming hints

ISO/IEC C cannot directly generate the WFI, WFE, and SEV instructions. The CMSIS provides the following intrinsic functions for these instructions:

```
void __WFE(void) // Wait for Event
void __WFI(void) // Wait for Interrupt
void __SEV(void) // Send Event
```
Chapter 3
The Cortex-M0 Instruction Set

This chapter describes the Cortex-M0 instruction set. It contains the following sections:

- *Instruction set summary* on page 3-2
- *Intrinsic functions* on page 3-5
- *About the instruction descriptions* on page 3-7
- *Memory access instructions* on page 3-16
- *General data processing instructions* on page 3-27
- *Branch and control instructions* on page 3-45
3.1 Instruction set summary

The processor implements a version of the Thumb instruction set. Table 3-1 lists the supported instructions.

--- Note ---

In Table 3-1:
- angle brackets, <>, enclose alternative forms of the operand
- braces, {}, enclose optional operands and mnemonic parts
- the Operands column is not exhaustive.

For more information on the instructions and operands, see the instruction descriptions.

3.2 Intrinsic functions

ISO/IEC C code cannot directly access some Cortex-M0 instructions. This section describes intrinsic functions that can generate these instructions, provided by the CMSIS and that might be provided by a C compiler. If a C compiler does not support an appropriate intrinsic function, you might have to use inline assembler to access the relevant instruction.

The CMSIS provides the following intrinsic functions to generate instructions that ISO/IEC C code cannot directly access:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>CMSIS intrinsic function</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPSIE i</td>
<td>void __enable_irq(void)</td>
</tr>
<tr>
<td>CPSID i</td>

</tbody>
</table>
3.3 About the instruction descriptions

The following sections give more information about using the instructions:

- *Operands* on page 3-8
- *Restrictions when using PC or SP* on page 3-8
- *Shift Operations* on page 3-8
- *Address alignment* on page 3-12
- *PC-relative expressions* on page 3-12
3.3.1 Operands

An instruction operand can be an ARM register, a constant, or another instruction-specific parameter. Instructions act on the operands and often store the result in a destination register. When there is a destination register in the instruction, it is usually specified before the other operands.

3.3.2 Restrictions when using PC or SP

Many instructions are unable to use, or have restrictions on whether you can use, the PC or SP for the operands or destination register. See instruction descriptions for more information.

Note

When you update the PC with a BX, BLX, or POP instruction, bit[0] of any address must be 1 for correct execution. This is because this bit indicates the destination instruction set, and the Cortex-M0 processor only supports Thumb instructions. When a BL or BLX instruction writes the value of bit[0] into the LR it is automatically assigned the value 1.

3.3.3 Shift Operations

Register shift operations move the bits in a register left or right by a specified number of bits, the shift length. Register shift can be performed directly by the instructions ASR, LSR, LSL, and ROR and the result is written to a destination register.

The permitted shift lengths depend on the shift type and the instruction, see the individual instruction description. If the shift length is 0, no shift occurs. Register shift operations update the carry flag except when the specified shift length is 0. The following sub-sections describe the various shift operations and how they affect the carry flag. In these descriptions, \( Rm \) is the register containing the value to be shifted, and \( n \) is the shift length.

**ASR**

Arithmetic shift right by \( n \) bits moves the left-hand \( 32-n \) bits of the register \( Rm \), to the right by \( n \) places, into the right-hand \( 32-n \) bits of the result, and it copies the original bit[31] of the register into the left-hand \( n \) bits of the result. See Figure 3-1 on page 3-9.

You can use the ASR operation to divide the signed value in the register \( Rm \) by \( 2^n \), with the result being rounded towards negative-infinity.

When the instruction is ASRS the carry flag is updated to the last bit shifted out, bit[\( n-1 \)], of the register \( Rm \).
• If \( n \) is 32 or more, then all the bits in the result are set to the value of bit[31] of \( Rm \).
• If \( n \) is 32 or more and the carry flag is updated, it is updated to the value of bit[31] of \( Rm \).

---

**LSR**

Logical shift right by \( n \) bits moves the left-hand 32-\( n \) bits of the register \( Rm \), to the right by \( n \) places, into the right-hand 32-\( n \) bits of the result, and it sets the left-hand \( n \) bits of the result to 0. See Figure 3-2.

You can use the LSR operation to divide the value in the register \( Rm \) by \( 2^n \), if the value is regarded as an unsigned integer.

When the instruction is LSRS, the carry flag is updated to the last bit shifted out, bit[\( n \)-1], of the register \( Rm \).

---

**Note**

• If \( n \) is 32 or more, then all the bits in the result are cleared to 0.
• If \( n \) is 33 or more and the carry flag is updated, it is updated to 0.
**LSL**

Logical shift left by \( n \) bits moves the right-hand 32-\( n \)-bits of the register \( R_m \), to the left by \( n \) places, into the left-hand 32-\( n \)-bits of the result, and it sets the right-hand \( n \) bits of the result to 0. See Figure 3-3.

You can use the LSL operation to multiply the value in the register \( R_m \) by \( 2^n \), if the value is regarded as an unsigned integer or a two’s complement signed integer. Overflow can occur without warning.

When the instruction is LSLS the carry flag is updated to the last bit shifted out, bit[32-\( n \)], of the register \( R_m \). These instructions do not affect the carry flag when used with LSL #0.

**Note**

- If \( n \) is 32 or more, then all the bits in the result are cleared to 0.
- If \( n \) is 33 or more and the carry flag is updated, it is updated to 0.

![Figure 3-3 LSL #3](image)

**ROR**

Rotate right by \( n \) bits moves the left-hand 32-\( n \)-bits of the register \( R_m \), to the right by \( n \) places, into the right-hand 32-\( n \)-bits of the result, and it moves the right-hand \( n \) bits of the register into the left-hand \( n \) bits of the result. See Figure 3-4 on page 3-11.

When the instruction is RORS the carry flag is updated to the last bit rotation, bit[\( n-1 \)], of the register \( R_m \).

**Note**

- If \( n \) is 32, then the value of the result is same as the value in \( R_m \), and if the carry flag is updated, it is updated to bit[31] of \( R_m \).
- ROR with shift length, \( n \), greater than 32 is the same as ROR with shift length \( n-32 \).
Figure 3-4 ROR #3
3.3.4 Address alignment

An aligned access is an operation where a word-aligned address is used for a word, or multiple word access, or where a halfword-aligned address is used for a halfword access. Byte accesses are always aligned.

There is no support for unaligned accesses on the Cortex-M0 processor. Any attempt to perform an unaligned memory access operation results in a HardFault exception.

3.3.5 PC-relative expressions

A PC-relative expression or label is a symbol that represents the address of an instruction or literal data. It is represented in the instruction as the PC value plus or minus a numeric offset. The assembler calculates the required offset from the label and the address of the current instruction. If the offset is too big, the assembler produces an error.

--- Note ---

- For most instructions, the value of the PC is the address of the current instruction plus 4 bytes.
- Your assembler might permit other syntaxes for PC-relative expressions, such as a label plus or minus a number, or an expression of the form \([PC, \#imm]\).
3.3.6 Conditional execution

Most data processing instructions update the condition flags in the APSR according to the result of the operation, see Application Program Status Register on page 2-6. Some instructions update all flags, and some only update a subset. If a flag is not updated, the original value is preserved. See the instruction descriptions for the flags they affect.

You can execute a conditional branch instruction, based on the condition flags set in another instruction, either:

- immediately after the instruction that updated the flags
- after any number of intervening instructions that have not updated the flags.

On the Cortex-M0 processor, conditional execution is available by using conditional branches.

This section describes:

- The condition flags on page 3-14
- Condition code suffixes on page 3-15.
The condition flags

The APSR contains the following condition flags:

N Set to 1 when the result of the operation was negative, cleared to 0 otherwise.

Z Set to 1 when the result of the operation was zero, cleared to 0 otherwise.

C Set to 1 when the operation resulted in a carry, cleared to 0 otherwise.

V Set to 1 when the operation caused overflow, cleared to 0 otherwise.

For more information about the APSR see Program Status Register on page 2-4.

A carry occurs:
• if the result of an addition is greater than or equal to $2^{32}$
• if the result of a subtraction is positive or zero
• as the result of a shift or rotate instruction.

Overflow occurs when the sign of the result, in bit[31], does not match the sign of the result had the operation been performed at infinite precision, for example:
• if adding two negative values results in a positive value
• if adding two positive values results in a negative value
• if subtracting a positive value from a negative value generates a positive value
• if subtracting a negative value from a positive value generates a negative value.

The Compare operations are identical to subtracting, for CMP, or adding, for CMN, except that the result is discarded. See the instruction descriptions for more information.
Condition code suffixes

Conditional branch is shown in syntax descriptions as $B\{cond\}$. A branch instruction with a condition code is only taken if the condition code flags in the APSR meet the specified condition, otherwise the branch instruction is ignored. Table 3-4 shows the condition codes to use.

Table 3-4 also shows the relationship between condition code suffixes and the N, Z, C, and V flags.

### Table 3-4 Condition code suffixes

<table>
<thead>
<tr>

</tbody>
</table>
3.4.1 ADR

Generates a PC-relative address.

Syntax

ADR Rd, label

where:

Rd is the destination register.

label is a PC-relative expression. See PC-relative expressions on page 3-12.

Operation

ADR generates an address by adding an immediate value to the PC, and writes the result to the destination register.

ADR facilitates the generation of position-independent code, because the address is PC-relative.

If you use ADR to generate a target address for a BX or BLX instruction, you must ensure that bit[0] of the address you generate is set to 1 for correct execution.

Restrictions

In this instruction Rd must specify R0-R7. The data-value addressed must be word aligned and within 1020 bytes of the current PC.

Condition flags

This instruction does not change the flags.

Examples

ADR R1, TextMessage ; Write address value of a location labelled as TextMessage to R1
ADR R3, [PC,#996] ; Set R3 to value of PC + 996.
3.4.2 LDR and STR, immediate offset

Load and Store with immediate offset.

Syntax

LDR  Rt, [<Rn | SP> {, #imm}]
LDR<B|H> Rt, [Rn {, #imm}]
STR  Rt, [<Rn | SP>, {,#imm}]
STR<B|H> Rt, [Rn {,#imm}]

where:
- Rt is the register to load or store.
- Rn is the register on which the memory address is based.
- imm is an offset from Rn. If imm is omitted, it is assumed to be zero.

Operation

LDR, LDRB and LDRH instructions load the register specified by Rt with either a word, byte or halfword data value from memory. Sizes less than word are zero extended to 32-bits before being written to the register specified by Rt.

STR, STRB and STRH instructions store the word, least-significant byte or lower halfword contained in the single register specified by Rt in to memory. The memory address to load from or store to is the sum of the value in the register specified by either Rn or SP and the immediate value imm.

Restrictions

In these instructions:

- Rt and Rn must only specify R0-R7.
- imm must be between:
  - 0 and 1020 and an integer multiple of four for LDR and STR using SP as the base register
  - 0 and 124 and an integer multiple of four for LDR and STR using R0-R7 as the base register
  - 0 and 62 and an integer multiple of two for LDRH and STRH
  - 0 and 31 for LDRB and STRB.
The computed address must be divisible by the number of bytes in the transaction, see Address alignment on page 3-12.

**Condition flags**

These instructions do not change the flags.

**Examples**

```
LDR    R4, [R7] ; Loads R4 from the address in R7.
STR    R2, [R0,#const-struc] ; const-struc is an expression evaluating to a constant in the range 0-1020.
```
3.4.3 LDR and STR, register offset

Load and Store with register offset.

Syntax

LDR Rt, [Rn, Rm]
LDR<B|H> Rt, [Rn, Rm]
LDR<SB|SH> Rt, [Rn, Rm]
STR Rt, [Rn, Rm]
STR<B|H> Rt, [Rn, Rm]

where:
Rt is the register to load or store.
Rn is the register on which the memory address is based.
Rm is a register containing a value to be used as the offset.

Operation

LDR, LDRB, LDRH, LDRSB and LDRSH load the register specified by Rt with either a word, zero extended byte, zero extended halfword, sign extended byte or sign extended halfword value from memory.

STR, STRB and STRH store the word, least-significant byte or lower halfword contained in the single register specified by Rt into memory.

The memory address to load from or store to is the sum of the values in the registers specified by Rn and Rm.
Restrictions

In these instructions:

- \( R_t, R_n, \) and \( R_m \) must only specify \( R_0-R_7 \).
- the computed memory address must be divisible by the number of bytes in the load or store, see Address alignment on page 3-12.

Condition flags

These instructions do not change the flags.

Examples

```
STR    R0, [R5, R1] ; Store value of R0 into an address equal to sum of R5 and R1
LDRSH  R1, [R2, R3] ; Load a halfword from the memory address specified by (R2 + R3), sign extend to 32-bits and write to R1.
```
3.4.4 LDR, PC-relative

Load register (literal) from memory.

**Syntax**

LDR Rt, label

where:

Rt is the register to load.

label is a PC-relative expression. See *PC-relative expressions* on page 3-12.

**Operation**

 Loads the register specified by Rt from the word in memory specified by label.

**Restrictions**

In these instructions, label must be within 1020 bytes of the current PC and word aligned.

**Condition flags**

These instructions do not change the flags.

**Examples**

LDR R0, LookUpTable ; Load R0 with a word of data from an address labelled as LookUpTable.

LDR R3, [PC, #100] ; Load R3 with memory word at (PC + 100).
3.4.5 LDM and STM

Load and Store Multiple registers.

**Syntax**

LDM $Rn!$, reglist

STM $Rn!$, reglist

where:

$Rn$ is the register on which the memory addresses are based.

! writeback suffix.

reglist is a list of one or more registers to be loaded or stored, enclosed in braces. It can contain register ranges. It must be comma separated if it contains more than one register or register range, see Examples on page 3-24.

LDMIA and LDMFD are synonyms for LDM. LDMIA refers to the base register being Incremented After each access. LDMFD refers to its use for popping data from Full Descending stacks.

STMIA and STMEA are synonyms for STM. STMIA refers to the base register being Incremented After each access. STMEA refers to its use for pushing data onto Empty Ascending stacks.

**Operation**

LDM instructions load the registers in reglist with word values from memory addresses based on $Rn$.

STM instructions store the word values in the registers in reglist to memory addresses based on $Rn$.

The memory addresses used for the accesses are at 4-byte intervals ranging from the value in the register specified by $Rn$ to the value in the register specified by $Rn + 4 * (n-1)$, where $n$ is the number of registers in reglist. The accesses happens in order of increasing register numbers, with the lowest numbered register using the lowest memory address and the highest number register using the highest memory address. If the writeback suffix is specified, the value in the register specified by $Rn + 4 * n$ is written back to the register specified by $Rn$. 
Restrictions

In these instructions:
- `reglist` and `Rn` are limited to R0-R7.
- the writeback suffix must always be used unless the instruction is an LDM where `reglist` also contains `Rn`, in which case the writeback suffix must not be used.
- the value in the register specified by `Rn` must be word aligned. See Address alignment on page 3-12 for more information.
- for STM, if `Rn` appears in `reglist`, then it must be the first register in the list.

Condition flags

These instructions do not change the flags.

Examples

```
LDM    R0,{R0,R3,R4} ; LDMIA is a synonym for LDM
STMIA  R1!,{R2-R4,R6}
```

Incorrect examples

```
STM    R5!,{R4,R5,R6} ; Value stored for R5 is unpredictable
LDM    R2,{} ; There must be at least one register in the list
```
3.4.6 PUSH and POP

Push registers onto, and pop registers off a full-descending stack.

Syntax

PUSH reglist
POP reglist

where:

reglist is a non-empty list of registers, enclosed in braces. It can contain register ranges. It must be comma separated if it contains more than one register or register range.

Operation

PUSH stores registers on the stack, with the lowest numbered register using the lowest memory address and the highest numbered register using the highest memory address.

POP loads registers from the stack, with the lowest numbered register using the lowest memory address and the highest numbered register using the highest memory address.

PUSH uses the value in the SP register minus four as the highest memory address, POP uses the value in the SP register as the lowest memory address, implementing a full-descending stack. On completion, PUSH updates the SP register to point to the location of the lowest store value, POP updates the SP register to point to the location above the highest location loaded.

If a POP instruction includes PC in its reglist, a branch to this location is performed when the POP instruction has completed. Bit[0] of the value read for the PC is used to update the APSR T-bit. This bit must be 1 to ensure correct operation.

Restrictions

In these instructions:

• reglist must use only R0-R7.
• The exception is LR for a PUSH and PC for a POP.

Condition flags

These instructions do not change the flags.
The Cortex-M0 Instruction Set

Examples

PUSH  \{R0,R4-R7\} ; Push R0,R4,R5,R6,R7 onto the stack
PUSH  \{R2,LR\}   ; Push R2 and the link-register onto the stack
POP   \{R0,R6,PC\} ; Pop r0,r6 and PC from the stack, then branch to
                   ; the new PC.
## 3.5 General data processing instructions

3.5.1 ADC, ADD, RSB, SBC, and SUB

Add with carry, Add, Reverse Subtract, Subtract with carry, and Subtract.

--- Note ---
Cortex-M0 supports the ADC, RSB, and SBC instructions only as instructions that update the flags, that is, as ADCS, RSBS, and SBCS.

**Syntax**

\[
\begin{align*}
\text{ADCS} & \quad \{Rd,\} \ Rn, \ Rm \\
\text{ADD(S)} & \quad \{Rd,\} \ Rn, <Rm|#imm> \\
\text{RSBS} & \quad \{Rd,\} \ Rn, \ Rm, \ #0 \\
\text{SBCS} & \quad \{Rd,\} \ Rn, \ Rm \\
\text{SUB(S)} & \quad \{Rd,\} \ Rn, <Rm|#imm>
\end{align*}
\]

Where:

- \( S \) causes an ADD or SUB instruction to update flags
- \( Rd \) specifies the result register
- \( Rn \) specifies the first source register
- \( Rm \) specifies the second source register
- \( imm \) specifies a constant immediate value.

When the optional \( Rd \) register specifier is omitted, it is assumed to take the same value as \( Rn \), for example \( ADDS \ R1,R2 \) is identical to \( ADDS \ R1,R1,R2 \).
The Cortex-M0 Instruction Set

**Operation**

The **ADCS** instruction adds the value in \( Rn \) to the value in \( Rm \), adding a further one if the carry flag is set, places the result in the register specified by \( Rd \) and updates the N, Z, C, and V flags.

The **ADD** instruction adds the value in \( Rn \) to the value in \( Rm \) or an immediate value specified by \( imm \) and places the result in the register specified by \( Rd \).

The **ADDS** instruction performs the same operation as **ADD** and also updates the N, Z, C and V flags.

The **RSBS** instruction subtracts the value in \( Rn \) from zero, producing the arithmetic negative of the value, and places the result in the register specified by \( Rd \) and updates the N, Z, C and V flags.

The **SBCS** instruction subtracts the value of \( Rm \) from the value in \( Rn \), deducts a further one if the carry flag is set. It places the result in the register specified by \( Rd \) and updates the N, Z, C and V flags.

The **SUB** instruction subtracts the value in \( Rm \) or the immediate specified by \( imm \). It places the result in the register specified by \( Rd \).

The **SUBS** instruction performs the same operation as **SUB** and also updates the N, Z, C and V flags.

Use **ADC** and **SBC** to synthesize multiword arithmetic, see *Examples* on page 3-32.

See also **ADR** on page 3-17.
Restrictions

Table 3-7 lists the legal combinations of register specifiers and immediate values that can be used with each instruction.

Table 3-7 ADC, ADD, RSB, SBC and SUB operand restrictions

<table>
<thead>

<td>R0-R7</td>
<td>-</td>
<td>-</td>
</tr>
</tbody>
</table>
Examples

Example 3-1 shows two instructions that add a 64-bit integer contained in R0 and R1 to another 64-bit integer contained in R2 and R3, and place the result in R0 and R1.

Example 3-1 64-bit addition

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Registers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDS</td>
<td>R0, R0, R2</td>
<td>add the least significant words</td>
</tr>
<tr>
<td>ADCS</td>
<td>R1, R1, R3</td>
<td>add the most significant words with carry</td>
</tr>
</tbody>
</table>

Multiword values do not have to use consecutive registers. Example 3-2 shows instructions that subtract a 96-bit integer contained in R1, R2, and R3 from another contained in R4, R5, and R6. The example stores the result in R4, R5, and R6.

Example 3-2 96-bit subtraction

<table>

</thead>
<tbody>
<tr>
<td>RSBS</td>
<td>R7, R7, #0</td>
<td>subtract R7 from zero</td>
</tr>
</tbody>
</table>

3.5.2 AND, ORR, EOR, and BIC

Logical AND, OR, Exclusive OR, and Bit Clear.

--- Note ---
Cortex-M0 supports the AND, ORR, EOR, and BIC instructions only as instructions that update the flags, that is, as ANDS, ORRS, EORS, and BICS.

---

Syntax

ANDS \{Rd,\} Rn, Rm
ORRS \{Rd,\} Rn, Rm
EORS \{Rd,\} Rn, Rm
BICS \{Rd,\} Rn, Rm

where:
Rd is the destination register.
Rn is the register holding the first operand and is the same as the destination register.
Rm second register.

Operation

The AND, EOR, and ORR instructions perform bitwise AND, exclusive OR, and inclusive OR operations on the values in Rn and Rm.

The BIC instruction performs an AND operation on the bits in Rn with the logical negation of the corresponding bits in the value of Rm.

The condition code flags are updated on the result of the operation, see The condition flags on page 3-14.
Restrictions

In these instructions, \( Rd \), \( Rn \), and \( Rm \) must only specify R0-R7.

Condition flags

These instructions:

- update the N and Z flags according to the result
- do not affect the C or V flag.

Examples

\[
\begin{align*}
\text{ANDS} & \quad R2, R2, R1 \\
\text{ORRS} & \quad R2, R2, R5 \\
\text{ANDS} & \quad R5, R5, R8 \\
\text{EORS} & \quad R7, R7, R6 \\
\text{BICS} & \quad R0, R0, R1
\end{align*}
\]
3.5.3 ASR, LSL, LSR, and ROR

Arithmetic Shift Right, Logical Shift Left, Logical Shift Right, and Rotate Right.

Syntax

\[
\begin{align*}
\text{ASRS} & \{Rd,\} Rm, Rs \\
\text{ASRS} & \{Rd,\} Rm, #imm \\
\text{LSLS} & \{Rd,\} Rm, Rs \\
\text{LSLS} & \{Rd,\} Rm, #imm \\
\text{LSRS} & \{Rd,\} Rm, Rs \\
\text{LSRS} & \{Rd,\} Rm, #imm \\
\text{RORS} & \{Rd,\} Rm, Rs \\
\end{align*}
\]

where:

- \(Rd\) is the destination register. If \(Rd\) is omitted, it is assumed to take the same value as \(Rm\).
- \(Rm\) is the register holding the value to be shifted.
- \(Rs\) is the register holding the shift length to apply to the value in \(Rm\).
- \(imm\) is the shift length. The range of shift length depends on the instruction:

\[
\begin{align*}
\text{ASR} & \quad \text{shift length from 1 to 32} \\
\text{LSL} & \quad \text{shift length from 0 to 31} \\
\text{LSR} & \quad \text{shift length from 1 to 32}.
\end{align*}
\]

Note

\(\text{MOVS} \ Rd, \ Rm\) is a pseudonym for \(\text{LSLS} \ Rd, \ Rm, \ #0\).

Operation

ASR, LSL, LSR, and ROR perform an arithmetic-shift-left, logical-shift-left, logical-shift-right or a right-rotation of the bits in the register \(Rm\) by the number of places specified by the immediate \(imm\) or the value in the least-significant byte of the register specified by \(Rs\).

For details on what result is generated by the different instructions, see Shift Operations on page 3-8.
Restrictions

In these instructions, \(Rd\), \(Rm\), and \(Rs\) must only specify \(R0\)-\(R7\). For non-immediate instructions, \(Rd\) and \(Rm\) must specify the same register.

Condition flags

These instructions update the N and Z flags according to the result.

The C flag is updated to the last bit shifted out, except when the shift length is 0, see Shift Operations on page 3-8. The V flag is left unmodified.

Examples

\[
\begin{align*}
\text{ASRS} & \quad R7, R5, #9 \quad ; \text{Arithmetic shift right by 9 bits} \\
\text{LSLS} & \quad R1, R2, #3 \quad ; \text{Logical shift left by 3 bits with flag update} \\
\text{LSRS} & \quad R4, R5, #6 \quad ; \text{Logical shift right by 6 bits} \\
\text{RORS} & \quad R4, R4, R6 \quad ; \text{Rotate right by the value in the bottom byte of R6.}
\end{align*}
\]
3.5.4 CMP and CMN

Compare and Compare Negative.

Syntax

CMN Rn, Rm

CMP Rn, #imm

CMP Rn, Rm

where:
Rn is the register holding the first operand.
Rm is the register to compare with.
imm is the immediate value to compare with.

Operation

These instructions compare the value in a register with either the value in another register or an immediate value. They update the condition flags on the result, but do not write the result to a register.

The CMP instruction subtracts either the value in the register specified by Rm, or the immediate imm from the value in Rn and updates the flags. This is the same as a SUBS instruction, except that the result is discarded.

The CMN instruction adds the value of Rm to the value in Rn and updates the flags. This is the same as an ADDS instruction, except that the result is discarded.

Restrictions

For the:

• CMN instruction Rn, and Rm must only specify R0-R7.

• CMP instruction:

  — Rn and Rm can specify R0-R14
  — immediate must be in the range 0-255.

Condition flags

These instructions update the N, Z, C and V flags according to the result.
Examples

CMP  R2, R9
CMN  R0, R2
3.5.5 MOV and MVN

Move and Move NOT.

Syntax

MOV{S} Rd, Rm
MOVS Rd, #imm
MVNS Rd, Rm

where:

S is an optional suffix. If S is specified, the condition code flags are updated on the result of the operation, see Conditional execution on page 3-13.

Rd is the destination register.

Rm is a register.

imm is any value in the range 0-255.

Operation

The MOV instruction copies the value of Rm into Rd.

The MOVS instruction performs the same operation as the MOV instruction, but also updates the N and Z flags.

The MVNS instruction takes the value of Rm, performs a bitwise logical negate operation on the value, and places the result into Rd.

Restrictions

In these instructions, Rd, and Rm must only specify R0-R7.

When Rd is the PC in a MOV instruction:

• Bit[0] of the result is discarded.

• A branch occurs to the address created by forcing bit[0] of the result to 0. The T-bit remains unmodified.

Note

Though it is possible to use MOV as a branch instruction, ARM strongly recommends the use of a BX or BLX instruction to branch for software portability.
Condition flags

If S is specified, these instructions:

- update the N and Z flags according to the result
- do not affect the C or V flags.

Example

```
MOVS R0, #0x000B ; Write value of 0x000B to R0, flags get updated
MOVS R1, #0x0 ; Write value of zero to R1, flags are updated
MOV R10, R12 ; Write value in R12 to R10, flags are not updated
MOV R3, #23 ; Write value of 23 to R3
MOV R8, SP ; Write value of stack pointer to R8
MVNS R2, R0 ; Write inverse of R0 to the R2 and update flags
```
3.5.6 MULS

Multiply using 32-bit operands, and producing a 32-bit result.

Syntax

MULS Rd, Rn, Rm

where:
Rd is the destination register.
Rn, Rm are registers holding the values to be multiplied.

Operation

The MUL instruction multiplies the values in the registers specified by Rn and Rm, and places the least significant 32 bits of the result in Rd. The condition code flags are updated on the result of the operation, see Conditional execution on page 3-13.

The results of this instruction does not depend on whether the operands are signed or unsigned.

Restrictions

In this instruction:
• Rd, Rn, and Rm must only specify R0-R7
• Rd must be the same as Rm.

Condition flags

This instruction:
• updates the N and Z flags according to the result
• does not affect the C or V flags.

Examples

MULS R0, R2, R0 ; Multiply with flag update, R0 = R0 x R2
3.5.7 REV, REV16, and REVSH

Reverse bytes.

Syntax

REV Rd, Rn
REV16 Rd, Rn
REVSH Rd, Rn

where:

Rd is the destination register.
Rn is the source register.

Operation

Use these instructions to change endianness of data:

REV converts 32-bit big-endian data into little-endian data or 32-bit little-endian data into big-endian data.

REV16 converts two packed 16-bit big-endian data into little-endian data or two packed 16-bit little-endian data into big-endian data.

REVSH converts 16-bit signed big-endian data into 32-bit signed little-endian data or 16-bit signed little-endian data into 32-bit signed big-endian data.

Restrictions

In these instructions, Rd, and Rn must only specify R0-R7.

Condition flags

These instructions do not change the flags.

Examples

REV R3, R7 ; Reverse byte order of value in R7 and write it to R3
REV16 R0, R0 ; Reverse byte order of each 16-bit halfword in R0
REVSH R0, R5 ; Reverse signed halfword
3.5.8 SXT and UXT

Sign extend and Zero extend.

**Syntax**

- `SXTB Rd, Rm`
- `SXTH Rd, Rm`
- `UXTB Rd, Rm`
- `UXTH Rd, Rm`

where:

- `Rd` is the destination register.
- `Rm` is the register holding the value to be extended.

**Operation**

These instructions extract bits from the resulting value:

- `SXTB` extracts bits[7:0] and sign extends to 32 bits
- `UXTB` extracts bits[7:0] and zero extends to 32 bits
- `SXTH` extracts bits[15:0] and sign extends to 32 bits
- `UXTH` extracts bits[15:0] and zero extends to 32 bits.

**Restrictions**

In these instructions, `Rd` and `Rm` must only specify R0-R7.

**Condition flags**

These instructions do not affect the flags.

**Examples**

- `SXTH R4, R6`; Obtain the lower halfword of the value in R6 and then sign extend to 32 bits and write the result to R4.
- `UXTB R3, R1`; Extract lowest byte of the value in R10 and zero extend it, and write the result to R3.
3.5.9 TST

Test bits.

Syntax

\text{TST } Rn, Rm

where:

\( Rn \) is the register holding the first operand.

\( Rm \) the register to test against.

Operation

This instruction tests the value in a register against another register. It updates the condition flags based on the result, but does not write the result to a register.

The \text{TST} instruction performs a bitwise AND operation on the value in \( Rn \) and the value in \( Rm \). This is the same as the \text{ANDS} instruction, except that it discards the result.

To test whether a bit of \( Rn \) is 0 or 1, use the \text{TST} instruction with a register that has that bit set to 1 and all other bits cleared to 0.

Restrictions

In these instructions, \( Rn \) and \( Rm \) must only specify R0-R7.

Condition flags

This instruction:

\begin{itemize}
  \item updates the N and Z flags according to the result
  \item does not affect the C or V flags.
\end{itemize}

Examples

\text{TST } R0, R1 ; Perform bitwise AND of R0 value and R1 value, 
\hfill ; condition code flags are updated but result is discarded
3.6 Branch and control instructions

Table 3-8 shows the branch and control instructions:

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Brief description</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>
<td>B(cc)</td>
<td>Branch {conditionally}</td>
<td>B, BL, BX, and BLX on page 3-46</td>
</tr>
<tr>
<td>BL</td>
<td>Branch with Link</td>
<td>B, BL, BX, and BLX on page 3-46</td>
</tr>
<tr>
<td>BLX</td>
<td>Branch indirect with Link</td>
<td>B, BL, BX, and BLX on page 3-46</td>
</tr>
<tr>
<td>BX</td>
<td>Branch indirect</td>
<td>B, BL, BX, and BLX on page 3-46</td>
</tr>
</tbody>
</table>
3.6.1  B, BL, BX, and BLX

Branch instructions.

**Syntax**

\[
\begin{align*}
B\{cond\} & \ label \\
BL & \ label \\
BX & \ Rm \\
BLX & \ Rm
\end{align*}
\]

where:

- **cond** is an optional condition code, see *Conditional execution* on page 3-13.
- **label** is a PC-relative expression. See *PC-relative expressions* on page 3-12.
- **Rm** is a register providing the address to branch to.

**Operation**

All these instructions cause a branch to the address indicated by **label** or contained in the register specified by **Rm**. In addition:

- The **BL** and **BLX** instructions write the address of the next instruction to **LR**, the link register **R14**.
- The **BX** and **BLX** instructions result in a HardFault exception if bit[0] of **Rm** is 0.

**BL** and **BLX** instructions also set bit[0] of the **LR** to 1. This ensures that the value is suitable for use by a subsequent **POP {PC}** or **BX** instruction to perform a successful return branch.

Table 3-9 shows the ranges for the various branch instructions.

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Branch range</th>
</tr>
</thead>
<tbody>
<tr>
<td>B label</td>
<td>−2KB to +2KB</td>
</tr>
<tr>
<td>B{cond} label</td>
<td>−256 bytes to +254 bytes</td>
</tr>
<tr>
<td>BL label</td>
<td>−16MB to +16MB</td>
</tr>
<tr>
<td>BX Rm</td>
<td>Any value in register</td>
</tr>
<tr>
<td>BLX Rm</td>
<td>Any value in register</td>
</tr>
</tbody>
</table>
Restrictions

In these instructions:

- Do not use SP or PC in the BX or BLX instruction.
- For BX and BLX, bit[0] of Rm must be 1 for correct execution. Bit[0] is used to update the EPSR T-bit and is discarded from the target address.

Note

Bcond is the only conditional instruction on the Cortex-M0 processor.

Condition flags

These instructions do not change the flags.

Examples

B loopA ; Branch to loopA
BL func ; Branch with link (Call) to function func, return address stored in LR
BX LR ; Return from function call
BLX R0 ; Branch with link and exchange (Call) to a address stored in R0
BEQ labelD ; Conditionally branch to labelD if last flag setting; instruction set the Z flag, else do not branch.
### 3.7 Miscellaneous instructions

Table 3-10 shows the remaining Cortex-M0 instructions:

3.7.1 BKPT

Breakpoint.

**Syntax**

BKPT #imm

where:

imm is an integer in the range 0-255.

**Operation**

The BKPT instruction causes the processor to enter Debug state. Debug tools can use this to investigate system state when the instruction at a particular address is reached.

imm is ignored by the processor. If required, a debugger can use it to store additional information about the breakpoint.

The processor might also produce a HardFault or go in to lockup if a debugger is not attached when a BKPT instruction is executed. See Lockup on page 2-27 for more information.

**Restrictions**

There are no restrictions.

**Condition flags**

This instruction does not change the flags.

**Examples**

    BKPT #0 ; Breakpoint with immediate value set to 0x0.
3.7.2 CPS

Change Processor State.

Syntax

CPSID i
CPSIE i

Operation

CPS changes the PRIMASK special register values. CPSID causes interrupts to be disabled by setting PRIMASK. CPSIE cause interrupts to be enabled by clearing PRIMASK. See Exception mask register on page 2-8 for more information about these registers.

Restrictions

There are no restrictions.

Condition flags

This instruction does not change the condition flags.

Examples

CPSID i ; Disable all interrupts except NMI (set PRIMASK)
CPSIE i ; Enable interrupts (clear PRIMASK)
3.7.3 DMB

Data Memory Barrier.

Syntax

DMB

Operation

DMB acts as a data memory barrier. It ensures that all explicit memory accesses that appear in program order before the DMB instruction are observed before any explicit memory accesses that appear in program order after the DMB instruction. DMB does not affect the ordering of instructions that do not access memory.

Restrictions

There are no restrictions.

Condition flags

This instruction does not change the flags.

Examples

DMB ; Data Memory Barrier
3.7.4 DSB

Data Synchronization Barrier.

Syntax

DSB

Operation

DSB acts as a special data synchronization memory barrier. Instructions that come after the DSB, in program order, do not execute until the DSB instruction completes. The DSB instruction completes when all explicit memory accesses before it complete.

Restrictions

There are no restrictions.

Condition flags

This instruction does not change the flags.

Examples

DSB ; Data Synchronisation Barrier
### 3.7.5 ISB

Instruction Synchronization Barrier.

**Syntax**

ISB

**Operation**

ISB acts as an instruction synchronization barrier. It flushes the pipeline of the processor, so that all instructions following the ISB are fetched from cache or memory again, after the ISB instruction has been completed.

**Restrictions**

There are no restrictions.

**Condition flags**

This instruction does not change the flags.

**Examples**

    ISB ; Instruction Synchronisation Barrier
3.7.6 MRS

Move the contents of a special register to a general-purpose register.

**Syntax**

MRS \( Rd, \ Spec\_reg \)

where:

\( Rd \) is the general-purpose destination register.

\( Spec\_reg \) is one of the special-purpose registers: APSR, IPSR, EPSR, IEPSR, IAPSR, EAPSR, PSR, MSP, PSP, PRIMASK, or CONTROL.

**Operation**

MRS stores the contents of a special-purpose register to a general-purpose register. The MRS instruction can be combined with the MSR instruction to produce read-modify-write sequences that are suitable for modifying a specific flag in the PSR.

See MSR on page 3-55.

**Restrictions**

In this instruction, \( Rd \) must not be SP or PC.

**Condition flags**

This instruction does not change the flags.

**Examples**

MRS R0, PRIMASK ; Read PRIMASK value and write it to R0
3.7.7 MSR

Move the contents of a general-purpose register into the specified special register.

Syntax

MSR spec_reg, Rn

where:

Rn is the general-purpose source register.

spec_reg is the special-purpose destination register: APSR, IPSR, EPSR, IEPSR, IAPSR, EAPSR, PSR, MSP, PSP, PRIMASK, or CONTROL.

Operation

MSR updates one of the special registers with the value from the register specified by Rn.

See MRS on page 3-54.

Restrictions

In this instruction, Rn must not be SP or PC.

Condition flags

This instruction updates the flags explicitly based on the value in Rn.

Examples

MSR CONTROL, R1 ; Read R1 value and write it to the CONTROL register
3.7.8 NOP

No operation.

Syntax

NOP

Operation

NOP performs no operation and is not guaranteed to be time consuming. The processor might remove it from the pipeline before it reaches the execution stage.

Use NOP for padding, for example to place the subsequent instructions on a 64-bit boundary.

Restrictions

There are no restrictions.

Condition flags

This instruction does not change the flags.

Examples

NOP ; No operation
3.7.9 SEV

Send Event.

Syntax
SEV

Operation
SEV causes an event to be signaled to all processors in a multiprocessor system. It also sets the local event register, see Power management on page 2-28.

See also WFE on page 3-59.

Restrictions
There are no restrictions.

Condition flags
This instruction does not change the flags.

Examples
SEV ; Send Event
3.7.10 SVC

Supervisor Call.

Syntax

SVC #imm

where:

imm is an integer in the range 0-255.

Operation

The SVC instruction causes the SVC exception.

imm is ignored by the processor. If required, it can be retrieved by the exception handler to determine what service is being requested.

Restrictions

There are no restrictions.

Condition flags

This instruction does not change the flags.

Examples

SVC #0x32 ; Supervisor Call (SVC handler can extract the immediate value by locating it using the stacked PC)
3.7.11  WFE

Wait For Event.

Syntax

WFE

Operation

If the event register is 0, WFE suspends execution until one of the following events occurs:

• an exception, unless masked by the exception mask registers or the current priority level
• an exception enters the Pending state, if SEVONPEND in the System Control Register is set
• a Debug Entry request, if debug is enabled
• an event signaled by a peripheral or another processor in a multiprocessor system using the SEV instruction.

If the event register is 1, WFE clears it to 0 and completes immediately.

For more information see Power management on page 2-28.

Note

WFE is intended for power saving only. When writing software assume that WFE might behave as NOP.

Restrictions

There are no restrictions.

Condition flags

This instruction does not change the flags.

Examples

WFE ; Wait for event
3.7.12  WFI

Wait for Interrupt.

Syntax

WFI

Operation

WFI suspends execution until one of the following events occurs:
• an exception
• an interrupt becomes pending, which would preempt if PRIMASK was clear
• a Debug Entry request, regardless of whether debug is enabled.

Note

WFI is intended for power saving only. When writing software assume that WFI might behave as a NOP operation.

Restrictions

There are no restrictions.

Condition flags

This instruction does not change the flags.

Examples

WFI ; Wait for interrupt
Chapter 4
Cortex-M0 Peripherals

This chapter describes the ARM Cortex-M0 core peripherals. It contains the following sections:

• *About the Cortex-M0 peripherals on page 4-2*
• *Nested Vectored Interrupt Controller on page 4-3*
• *System Control Block on page 4-11*
• *Optional system timer, SysTick on page 4-21.*
4.1 About the Cortex-M0 peripherals

The address map of the PPB is:

<table>
<thead>
<tr>
<th>Address</th>
<th>Core peripheral</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xE000E008-0xE000E00F</td>
<td>System Control Block</td>
<td>Table 4-10 on page 4-11</td>
</tr>
<tr>
<td>0xE000E010-0xE000E01F</td>
<td>Reserved</td>
<td>-</td>
</tr>
<tr>
<td>0xE000E010-0xE000E01F</td>
<td>SysTick system timer a</td>
<td>Table 4-19 on page 4-21</td>
</tr>
<tr>
<td>0xE000E100-0xE000E4EF</td>
<td>Nested Vectored Interrupt Controller</td>
<td>Table 4-2 on page 4-3</td>
</tr>
<tr>
<td>0xE000ED00-0xE000ED3F</td>
<td>System Control Block</td>
<td>Table 4-10 on page 4-11</td>
</tr>
<tr>
<td>0xE000EF00-0xE000EF03</td>
<td>Nested Vectored Interrupt Controller</td>
<td>Table 4-2 on page 4-3</td>
</tr>
</tbody>
</table>

a. This address range is reserved if your device does not implement SysTick.

In register descriptions, the register type is described as follows:

- **RW** Read and write.
- **RO** Read-only.
- **WO** Write-only.
4.2 Nested Vectored Interrupt Controller

This section describes the NVIC and the registers it uses. The NVIC supports:

- An implementation-defined number of interrupts, in the range 1-32.
- A programmable priority level of 0-192 in steps of 64 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority.
- Level and pulse detection of interrupt signals.
- Interrupt tail-chaining.
- An external NMI.

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead. This provides low latency exception handling. The hardware implementation of the NVIC registers is:

<table>
<thead>
<tr>
<th>Address</th>
<th>Name</th>
<th>Type</th>
<th>Reset value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

4.2.1 Accessing the Cortex-M0 NVIC registers using CMSIS

CMSIS functions enable software portability between different Cortex-M profile processors.

To access the NVIC registers when using CMSIS, use the following functions:

<table>
<thead>
<tr>
<th>CMSIS function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void NVIC_EnableIRQ(IRQn_Type IRQn)</td>
<td>Enables an interrupt or exception.</td>
</tr>
<tr>
<td>void NVIC_DisableIRQ(IRQn_Type IRQn)</td>
<td>Disables an interrupt or exception.</td>
</tr>
<tr>
<td>void NVIC_SetPendingIRQ(IRQn_Type IRQn)</td>
<td>Sets the pending status of interrupt or exception to 1.</td>
</tr>
</tbody>
</table>
4.2.2 Interrupt Set-enable Register

The ISER enables interrupts, and shows the interrupts that are enabled. See the register summary in Table 4-2 on page 4-3 for the register attributes.

The bit assignments are:

```
+-------------------------+-------------------------+-------------------------+-------------------------+-------------------------+-------------------------+-------------------------+
|                         |                         |                         |                         |                         |                         |                         |
|     31                   | 30                      | 29                      | 28                      | 27                      | 26                      | 25                      |
|                         |                         |                         |                         |                         |                         | [1:0] SETENA bits       |
+-------------------------+-------------------------+-------------------------+-------------------------+-------------------------+-------------------------+-------------------------+
```

Table 4-4 ISER bit assignments

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>SETENA</td>
<td>Interrupt set-enable bits.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Write:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = no effect</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = enable interrupt.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Read:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = interrupt disabled</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = interrupt enabled</td>
</tr>
</tbody>
</table>

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.
4.2.3 Interrupt Clear-enable Register

The ICER disables interrupts, and shows the interrupts that are enabled. See the register summary in Table 4-2 on page 4-3 for the register attributes.

The bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>CLRENA bits</td>
</tr>
</tbody>
</table>

Table 4-5 ICER bit assignments

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>CLRENA</td>
<td>Interrupt clear-enable bits.</td>
</tr>
<tr>
<td>Write:</td>
<td></td>
<td>0 = no effect</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = disable interrupt.</td>
</tr>
<tr>
<td>Read:</td>
<td></td>
<td>0 = interrupt disabled</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = interrupt enabled.</td>
</tr>
</tbody>
</table>

4.2.4 Interrupt Set-pending Register

The ISPR forces interrupts into the pending state, and shows the interrupts that are pending. See the register summary in Table 4-2 on page 4-3 for the register attributes.

The bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>SETPEND bits</td>
</tr>
</tbody>
</table>

Table 4-5 ICER bit assignments
Writing 1 to the ISPR bit corresponding to:
- an interrupt that is pending has no effect
- a disabled interrupt sets the state of that interrupt to pending.

### 4.2.5 Interrupt Clear-pending Register

The ICPR removes the pending state from interrupts, and shows the interrupts that are pending. See the register summary in Table 4-2 on page 4-3 for the register attributes.

The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:0]</td>
<td>CLRPEND</td>
<td>Interrupt clear-pending bits. Write: 0 = no effect 1 = removes pending state an interrupt. Read: 0 = interrupt is not pending 1 = interrupt is pending.</td>
</tr>
</tbody>
</table>
4.2.6 Interrupt Priority Registers

The interrupt priority registers provide an 8-bit priority field for each interrupt, and each register holds four priority fields. This means the number of registers is implementation-defined, and corresponds to the number of implemented interrupts. These registers are only word-accessible. See the register summary in Table 4-2 on page 4-3 for their attributes. For an implementation that supports 32 interrupts the registers are IPR0-IPR7, as shown:

See Accessing the Cortex-M0 NVIC registers using CMSIS on page 4-3 for more information about the access to the interrupt priority array, which provides the software view of the interrupt priorities.

Find the IPR number and byte offset for interrupt \( M \) as follows:

\[ \text{the corresponding IPR number, } N, \text{ is given by } N = N \div 4 \]
• the byte offset of the required Priority field in this register is \( M \ MOD 4 \), where:
  — byte offset 0 refers to register bits[7:0]
  — byte offset 1 refers to register bits[15:8]
  — byte offset 2 refers to register bits[23:16]
  — byte offset 3 refers to register bits[31:24].

4.2.7 Level-sensitive and pulse interrupts

A Cortex-M0 device can support both level-sensitive and pulse interrupts. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt, see Hardware and software control of interrupts. For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. This means that the peripheral can hold the interrupt signal asserted until it no longer requires servicing.

See the documentation supplied by your device vendor for details of which interrupts are level-sensitive and which are pulsed.

Hardware and software control of interrupts

The Cortex-M0 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

• the NVIC detects that the interrupt signal is active and the corresponding interrupt is not active
• the NVIC detects a rising edge on the interrupt signal
• software writes to the corresponding interrupt set-pending register bit, see Interrupt Set-pending Register on page 4-5.
A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt. This changes the state of the interrupt from pending to active. Then:
  - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR.
    If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.

- Software writes to the corresponding interrupt clear-pending register bit.
  For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
  For a pulse interrupt, state of the interrupt changes to:
    - inactive, if the state was pending
    - active, if the state was active and pending.

### 4.2.8 NVIC usage hints and tips

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers.

An interrupt can enter pending state even if it is disabled. Disabling an interrupt only prevents the processor from taking that interrupt.

**NVIC programming hints**

Software uses the CPSIE i and CPSID i instructions to enable and disable interrupts. The CMSIS provides the following intrinsic functions for these instructions:

```c
void __disable_irq(void) // Disable Interrupts
void __enable_irq(void) // Enable Interrupts
```
In addition, the CMSIS provides a number of functions for NVIC control, including:

<table>
<thead>
<tr>
<th>CMSIS interrupt control function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void NVIC_EnableIRQ(IRQn_t IRQn)</td>
<td>Enable IRQn</td>
</tr>
<tr>
<td>void NVIC_DisableIRQ(IRQn_t IRQn)</td>
<td>Disable IRQn</td>
</tr>
<tr>
<td>uint32_t NVIC_GetPendingIRQ (IRQn_t IRQn)</td>
<td>Return true (1) if IRQn is pending</td>
</tr>
<tr>
<td>void NVIC_SetPendingIRQ (IRQn_t IRQn)</td>
<td>Set IRQn pending</td>
</tr>
<tr>
<td>void NVIC_ClearPendingIRQ (IRQn_t IRQn)</td>
<td>Clear IRQn pending status</td>
</tr>
<tr>
<td>void NVIC_SetPriority (IRQn_t IRQn, uint32_t priority)</td>
<td>Set priority for IRQn</td>
</tr>
<tr>
<td>uint32_t NVIC_GetPriority (IRQn_t IRQn)</td>
<td>Read priority of IRQn</td>
</tr>
<tr>
<td>void NVIC_SystemReset (void)</td>
<td>Reset the system</td>
</tr>
</tbody>
</table>

The input parameter IRQn is the IRQ number, see Table 2-11 on page 2-20 for more information. For more information about these functions, see the CMSIS documentation.
4.3 System Control Block

The SCB provides system implementation information, and system control. This includes configuration, control, and reporting of the system exceptions. The SCB registers are:

Table 4-10 Summary of the SCB registers

<table>
<thead>
<tr>

<td>System Handler Priority Register 3 on page 4-20</td>
</tr>
</tbody>
</table>

a. See the register description for more information.

4.3.1 The CMSIS mapping of the Cortex-M0 SCB registers

To improve software efficiency, the CMSIS simplifies the SCB register presentation. In the CMSIS, the array SHP[1] corresponds to the registers SHPR2-SHPR3.

4.3.2 CPUID Register

The CPUID register contains the processor part number, version, and implementation information. See the register summary in Table 4-10 for its attributes. The reset value depends on the variant and patch values of the implemented device. The bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th>20</th>
<th>19</th>
<th>16</th>
<th>15</th>
<th>4</th>
<th>3</th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>Implementer</td>
<td>Variant</td>
<td>Constant</td>
<td>Partno</td>
<td>Revision</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
## 4.3.3 Interrupt Control and State Register

The ICSR:

- provides:
  - a set-pending bit for the NMI exception
  - set-pending and clear-pending bits for the PendSV and SysTick exceptions
- indicates:
  - the exception number of the exception being processed
  - whether there are preempted active exceptions
  - the exception number of the highest priority pending exception
  - whether any interrupts are pending.

### Table 4-11 CPUID register bit assignments

<td>0 = PendSV exception is not pending</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 = PendSV exception is pending.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Writing 1 to this bit is the only way to set the PendSV exception state</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>to pending.</td>
</tr>
</tbody>
</table>

Table 4-12 ICSR bit assignments
<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[27]</td>
<td>PENDSVCLR</td>
<td>WO</td>
<td>PendSV clear-pending bit. Write: 0 = no effect 1 = removes the pending state from the PendSV exception.</td>
</tr>
<tr>
<td>[26]</td>
<td>PENDSTSET</td>
<td>RW</td>
<td>SysTick exception set-pending bit. Write: 0 = no effect 1 = changes SysTick exception state to pending. Read: 0 = SysTick exception is not pending 1 = SysTick exception is pending. If your device does not implement the SysTick timer, this bit is Reserved.</td>
</tr>
<tr>
<td>[25]</td>
<td>PENDSTCLR</td>
<td>WO</td>
<td>SysTick exception clear-pending bit. Write: 0 = no effect 1 = removes the pending state from the SysTick exception. This bit is WO. On a register read its value is Unknown. If your device does not implement the SysTick timer, this bit is Reserved.</td>
</tr>
<tr>
<td>[22]</td>
<td>ISRPENDING</td>
<td>RO</td>
<td>Interrupt pending flag, excluding NMI and Faults: 0 = interrupt not pending 1 = interrupt pending.</td>
</tr>
<tr>
<td>[17:12]</td>
<td>VECTPENDING</td>
<td>RO</td>
<td>Indicates the exception number of the highest priority pending enabled exception: 0 = no pending exceptions Nonzero = the exception number of the highest priority pending enabled exception.</td>
</tr>
</tbody>
</table>
When you write to the ICSR, the effect is Unpredictable if you:
- write 1 to the PENDSVSET bit and write 1 to the PENDSVCLR bit
- write 1 to the PENDSTSET bit and write 1 to the PENDSTCLR bit.

### 4.3.4 Application Interrupt and Reset Control Register

The AIRCR provides endian status for data accesses and reset control of the system. See the register summary in Table 4-10 on page 4-11 and Table 4-13 on page 4-16 for its attributes.

To write to this register, you must write 0x05FA to the VECTKEY field, otherwise the processor ignores the write.

The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Type</th>
<th>Function</th>
</tr>
</thead>
</table>
| [5:0] | VECTACTIVEa | RO | Contains the active exception number:  
  0 = Thread mode  
  Nonzero = The exception numbera of the currently active exception.  
  
  **Note**  
  Subtract 16 from this value to obtain the CMSIS IRQ number that identifies the corresponding bit in the Interrupt Clear-Enable, Set-Enable, Clear-Pending, Set-pending, and Priority Register, see Table 2-5 on page 2-7.  
  
  a. This is the same value as IPSR bits[5:0], see *Interrupt Program Status Register* on page 2-7.

When you write to the ICSR, the effect is Unpredictable if you:
- write 1 to the PENDSVSET bit and write 1 to the PENDSVCLR bit
- write 1 to the PENDSTSET bit and write 1 to the PENDSTCLR bit.
4.3.5 System Control Register

The SCR controls features of entry to and exit from low power state. See the register summary in Table 4-10 on page 4-11 for its attributes. The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>

### 4.3.6 Configuration and Control Register

The CCR is a read-only register and indicates some aspects of the behavior of the Cortex-M0 processor. See the register summary in Table 4-10 on page 4-11 for the CCR attributes.
The bit assignments are:

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:10]</td>
<td>-</td>
<td>Reserved.</td>
</tr>
<tr>
<td>[9]</td>
<td>STKALIGN</td>
<td>Always reads as one, indicates 8-byte stack alignment on exception entry. On exception entry, the processor uses bit[9] of the stacked PSR to indicate the stack alignment. On return from the exception it uses this stacked bit to restore the correct stack alignment.</td>
</tr>
<tr>
<td>[3]</td>
<td>UNALIGN_TRP</td>
<td>Always reads as one, indicates that all unaligned accesses generate a HardFault.</td>
</tr>
<tr>
<td>[2:0]</td>
<td>-</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

4.3.7 System Handler Priority Registers

The SHPR2-SHPR3 registers set the priority level, 0 to 192, of the exception handlers that have configurable priority.

SHPR2-SHPR3 are word accessible. See the register summary in Table 4-10 on page 4-11 for their attributes.

To access the system exception priority level using CMSIS, use the following CMSIS functions:

- uint32_t NVIC_GetPriority(IRQn_Type IRQn)
- void NVIC_SetPriority(IRQn_Type IRQn, uint32_t priority)

The input parameter IRQn is the IRQ number, see Table 2-11 on page 2-20 for more information.
The system fault handlers, and the priority field and register for each handler are:

### Table 4-16 System fault handler priority fields

<table>
<thead>
<tr>
<th>Handler</th>
<th>Field</th>
<th>Register description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVCall</td>
<td>PRI_11</td>
<td>System Handler Priority Register 2</td>
</tr>
<tr>
<td>PendSV</td>
<td>PRI_14</td>
<td>System Handler Priority Register 3 on page 4-20</td>
</tr>
<tr>
<td>SysTick</td>
<td>PRI_15</td>
<td></td>
</tr>
</tbody>
</table>

Each PRI_N field is 8 bits wide, but the processor implements only bits[7:6] of each field, and bits[5:0] read as zero and ignore writes.

#### System Handler Priority Register 2

The bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>24</th>
<th>23</th>
<th></th>
<th></th>
<th>0</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRI_11</td>
<td></td>
<td>Reserved</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<td>PRI_14</td>
<td>Priority of system handler 14, PendSV</td>
</tr>
<tr>
<td>[15:0]</td>
<td>-</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

<sup>a</sup> This field is Reserved if your device does not implement the SysTick timer.

### 4.3.8 SCB usage hints and tips

Ensure software uses aligned 32-bit word size transactions to access all the SCB registers.
4.4 Optional system timer, SysTick

If implemented, when enabled, the timer counts down from the reload value to zero, reloads (wraps to) the value in the SYST_RVR on the next clock cycle, then decrements on subsequent clock cycles. Writing a value of zero to the SYST_RVR disables the counter on the next wrap. When the counter transitions to zero, the COUNTFLAG status bit is set to 1. Reading SYST_CSR clears the COUNTFLAG bit to 0.

Writing to the SYST_CVR clears the register and the COUNTFLAG status bit to 0. The write does not trigger the SysTick exception logic. Reading the register returns its value at the time it is accessed.

**Note**
When the processor is halted for debugging the counter does not decrement.

The system timer registers are:

<table>
<thead>
<tr>
<th>Address</th>
<th>Name</th>
<th>Type</th>
<th>Reset value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xE000E010</td>

<td>RO</td>
<td>- ^</td>
<td>SysTick Calibration Value Register on page 4-24</td>
</tr>
</tbody>
</table>

^ a. See the register description for more information.
4.4.1 SysTick Control and Status Register

The SYST_CSR enables the SysTick features. See the register summary in Table 4-19 on page 4-21 for its attributes. The register resets to 0x00000000, or 0x00000002 if your device does not implement a reference clock. The bit assignments are:

Table 4-20 SYST_CSR bit assignments

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:17]</td>
<td>Reserved</td>
<td>Reserved.</td>
</tr>
<tr>
<td>[16]</td>
<td>COUNTFLAG</td>
<td>Returns 1 if timer counted to 0 since the last read of this register.</td>
</tr>
<tr>
<td>[2]</td>
<td>CLKSOURCE</td>
<td>Selects the SysTick timer clock source:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = reference clock</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = processor clock.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If your device does not implement a reference clock, this bit reads-as-one and ignores writes.</td>
</tr>
<tr>
<td>[1]</td>
<td>TICKINT</td>
<td>Enables SysTick exception request:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = counting down to zero does not assert the SysTick exception request</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = counting down to zero to asserts the SysTick exception request.</td>
</tr>
<tr>
<td>[0]</td>
<td>ENABLE</td>
<td>Enables the counter:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = counter disabled</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = counter enabled.</td>
</tr>
</tbody>
</table>
4.4.2 SysTick Reload Value Register

The SYST_RVR specifies the start value to load into the SYST_CVR. See the register summary in Table 4-19 on page 4-21 for its attributes. The bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>RELOAD</td>
<td>Value to load into the SYST_CVR when the counter is enabled and when it reaches 0, see Calculating the RELOAD value.</td>
</tr>
</tbody>
</table>

Table 4-21 SYST_RVR bit assignments

Calculating the RELOAD value

The RELOAD value can be any value in the range 0xFFFFFFFF-0x00000001. You can program a value of 0, but this has no effect because the SysTick exception request and COUNTFLAG are activated when counting from 1 to 0.

To generate a multi-shot timer with a period of N processor clock cycles, use a RELOAD value of N-1. For example, if the SysTick interrupt is required every 100 clock pulses, set RELOAD to 99.

4.4.3 SysTick Current Value Register

The SYST_CVR contains the current value of the SysTick counter. See the register summary in Table 4-19 on page 4-21 for its attributes. The bit assignments are:

<table>
<thead>
<tr>
<th>Bit</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>CURRENT</td>
<td></td>
</tr>
</tbody>
</table>

Reserved
4.4.4 SysTick Calibration Value Register

The SYST_CALIB register indicates the SysTick calibration properties. See the register summary in Table 4-19 on page 4-21 for its attributes. The reset value of this register is implementation-defined. See the documentation supplied by your device vendor for more information about the meaning of the SYST_CALIB field values.

Table 4-22 SYST_CVR bit assignments

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
</table>
| [23:0] | CURRENT | Reads return the current value of the SysTick counter.  
|        |       | A write of any value clears the field to 0, and also clears the SYST_CSR.COUNTFLAG bit to 0. |

Table 4-23 SYST_CALIB register bit assignments

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
</table>
| [31]   | NOREF | Indicates whether the device provides a reference clock to the processor:  
|        |      | 0 = reference clock provided  
|        |      | 1 = reference clock provided.  
|        |      | If your device does not provide a reference clock, the SYST_CSR.CLKSOURCE bit reads-as-one and ignores writes. |
| [30]   | SKEW | Indicates whether the TENMS value is exact:  
|        |      | 0 = TENMS value is exact  
|        |      | 1 = TENMS value is inexact, or not given.  
|        |      | An inexact TENMS value can affect the suitability of SysTick as a software real time clock. |
| [23:0] | TENMS | Reload value for 10ms (100Hz) timing, subject to system clock skew errors. If the value reads as zero, the calibration value is not known.  
|        |      | If calibration information is not known, calculate the calibration value required from the frequency of the processor clock or external clock. |
4.4.5 SysTick usage hints and tips

The interrupt controller clock updates the SysTick counter. Some implementations stop this clock signal for low power mode. If this happens, the SysTick counter stops.

Ensure software uses word accesses to access the SysTick registers.

The SysTick counter reload and current value are not initialized by hardware. This means the correct initialization sequence for the SysTick counter is:

1. Program the reload value.
2. Clear the current value.
3. Program the Control and Status register.
Appendix A
Cortex-M0 Options

This appendix describes the configuration options for a Cortex-M0 processor implementation. This means it shows what features of a Cortex-M0 implementation are determined by the device manufacturer. It contains the following section:

• Cortex-M0 implementation options on page A-2.
A.1 Cortex-M0 implementation options

Table A-1 shows the Cortex-M0 implementation options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description, and affected documentation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of interrupts</td>
<td>The implementer decides how many interrupts the Cortex-M0 implementation supports, in the range 1-32. This affects the range of IRQ values in Table 2-5 on page 2-7.</td>
</tr>
<tr>
<td>Inclusion of the WIC</td>
<td>The implementer decides whether to include the Wakeup interrupt Controller (WIC), see The optional Wakeup Interrupt Controller on page 2-30.</td>
</tr>
<tr>
<td>Sleep mode power-saving</td>
<td>The implementer decides what sleep modes to implement, and the power-saving measures associated with any implemented mode, see Power management on page 2-28.</td>
</tr>
<tr>
<td>Endianness</td>
<td>The implementer decides whether the memory system is little-endian or big-endian, see Data types on page 2-10 and Memory endianness on page 2-17.</td>
</tr>
<tr>
<td>Memory features</td>
<td>Some features of the memory system are implementation-specific. This means that Memory model on page 2-12 cannot completely describe the memory map for a specific Cortex-M0 implementation.</td>
</tr>
<tr>
<td>SysTick timer</td>
<td>The SysTick timer and its SYST_CALIB register are implementation-defined. This can affect:</td>
</tr>
<tr>
<td></td>
<td>• System timer, Optional system timer, SysTick on page 4-21</td>
</tr>
<tr>
<td></td>
<td>• The entry for SYST_CALIB in Table 4-19 on page 4-20</td>
</tr>
<tr>
<td></td>
<td>• SysTick Calibration Value Register on page 4-22.</td>
</tr>
</tbody>
</table>
Glossary

This glossary describes some of the terms used in technical documents from ARM.

**Aligned**
A data item stored at an address that is divisible by the number of bytes that defines the data size is said to be aligned. Aligned words and halfwords have addresses that are divisible by four and two respectively. The terms word-aligned and halfword-aligned therefore stipulate addresses that are divisible by four and two respectively.

**Base register**
In instruction descriptions, a register specified by a load or store instruction that is used to hold the base value for the instruction’s address calculation. Depending on the instruction and its addressing mode, an offset can be added to or subtracted from the base register value to form the address that is sent to memory.

*See also* Index register.

**Big-endian (BE)**
Byte ordering scheme in which bytes of decreasing significance in a data word are stored at increasing addresses in memory.

*See also* Byte-invariant, Endianness, Little-endian.

**Big-endian memory**
Memory in which:

- a byte or halfword at a word-aligned address is the most significant byte or halfword within the word at that address
• a byte at a halfword-aligned address is the most significant byte within the halfword at that address.

See also Little-endian memory.

Breakpoint
A breakpoint is a mechanism provided by debuggers to identify an instruction at which program execution is to be halted. Breakpoints are inserted by the programmer to enable inspection of register contents, memory locations, variable values at fixed points in the program execution to test that the program is operating correctly. Breakpoints are removed after the program is successfully tested.

Byte-invariant
In a byte-invariant system, the address of each byte of memory remains unchanged when switching between little-endian and big-endian operation. When a data item larger than a byte is loaded from or stored to memory, the bytes making up that data item are arranged into the correct order depending on the endianness of the memory access. An ARM byte-invariant implementation also supports unaligned halfword and word memory accesses. It expects multi-word accesses to be word-aligned.

Cache
A block of on-chip or off-chip fast access memory locations, situated between the processor and main memory, used for storing and retrieving copies of often used instructions, data, or instructions and data. This is done to greatly increase the average speed of memory accesses and so improve processor performance.

Conditional execution
If the condition code flags indicate that the corresponding condition is true when the instruction starts executing, it executes normally. Otherwise, the instruction does nothing.

Context
The environment that each process operates in for a multitasking operating system. In ARM processors, this is limited to mean the physical address range that it can access in memory and the associated memory access permissions.

Debugger
A debugging system that includes a program, used to detect, locate, and correct software faults, together with custom hardware that supports software debugging.

Direct Memory Access (DMA)
An operation that accesses main memory directly, without the processor performing any accesses to the data concerned.

Endianness
Byte ordering. The scheme that determines the order that successive bytes of a data word are stored in memory. An aspect of the system's memory mapping.

See also Little-endian and Big-endian
Exception

An event that interrupts program execution. When an exception occurs, the processor suspends the normal program flow and starts execution at the address indicated by the corresponding exception vector. The indicated address contains the first instruction of the handler for the exception.

An exception can be an interrupt request, a fault, or a software-generated system exception. Faults include attempting an invalid memory access, attempting to execute an instruction in an invalid processor state, and attempting to execute an undefined instruction.

Exception vector

See Interrupt vector.

Halfword

A 16-bit data item.

Implementation-defined

The behavior is not architecturally defined, but is defined and documented by individual implementations.

Implementation-specific

The behavior is not architecturally defined, and does not have to be documented by individual implementations. Used when there are a number of implementation options available and the option chosen does not affect software compatibility.

Index register

In some load and store instruction descriptions, the value of this register is used as an offset to be added to or subtracted from the base register value to form the address that is sent to memory. Some addressing modes optionally enable the index register value to be shifted prior to the addition or subtraction.

See also Base register.

Interrupt handler

A program that control of the processor is passed to when an interrupt occurs.

Interrupt vector

One of a number of fixed addresses in low memory, or in high memory if high vectors are configured, that contains the first instruction of the corresponding interrupt handler.

Little-endian (LE)

Byte ordering scheme in which bytes of increasing significance in a data word are stored at increasing addresses in memory.

See also Big-endian, Byte-invariant, Endianness.

Little-endian memory

Memory in which:

- a byte or halfword at a word-aligned address is the least significant byte or halfword within the word at that address
• a byte at a halfword-aligned address is the least significant byte within the halfword at that address.

See also Big-endian memory.

Read
Reads are defined as memory operations that have the semantics of a load. Reads include the Thumb instructions LDM, LDR, LDRSH, LDRH, LDRSB, LDRB, and POP.

Region
A partition of memory space.

Reserved
A field in a control register or instruction format is reserved if the field is to be defined by the implementation, or produces Unpredictable results if the contents of the field are not zero. These fields are reserved for use in future extensions of the architecture or are implementation-specific. All reserved bits not used by the implementation must be written as 0 and read as 0.

Thumb instruction
One or two halfwords that specify an operation for a processor to perform. Thumb instructions must be halfword-aligned.

Unaligned
A data item stored at an address that is not divisible by the number of bytes that defines the data size is said to be unaligned. For example, a word stored at an address that is not divisible by four.

Undefined
 Indicates an instruction that generates an Undefined instruction exception.

Unpredictable
You cannot rely on the behavior. Unpredictable behavior must not represent security holes. Unpredictable behavior must not halt or hang the processor, or any parts of the system.

Warm reset
Also known as a core reset. Initializes the majority of the processor excluding the debug controller and debug logic. This type of reset is useful if you are using the debugging features of a processor.

WA
See Write-allocate.

WB
See Write-back.

Word
A 32-bit data item.

Write
Writes are defined as operations that have the semantics of a store. Writes include the Thumb instructions STM, STR, STRH, STRB, and PUSH.

Write-allocate (WA)
In a write-allocate cache, a cache miss on storing data causes a cache line to be allocated into the cache.

Write-back (WB)
In a write-back cache, data is only written to main memory when it is forced out of the cache on line replacement following a cache miss. Otherwise, writes by the processor only update the cache. This is also known as copyback.

<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Write buffer</td>
<td>A block of high-speed memory, arranged as a FIFO buffer, between the data cache and main memory, whose purpose is to optimize stores to main memory.</td>
</tr>
<tr>
<td>Write-through (WT)</td>
<td>In a write-through cache, data is written to main memory at the same time as the cache is updated.</td>
</tr>
<tr>
<td>WT</td>
<td>See Write-through.</td>
</tr>
